THE ENCYCLOPÆDIA BRITANNICA FOURTEENTH EDITION

VOLUME 12 HYDROZOA TO JEREMY. EPISTLE OF

HYDROZOA. The Hydrozoa (sometimes called Hydromedusae) are a class of animals, the vast majority of which are marine, and which belong to the still greater assemblage known as the Coelenterata (*q.v.*).

The Hydrozoa include not only polyps, but also medusae or jellyfish (these terms are defined in the article COELENTERATA). They are, in fact, that group of Coelenterata in which neither the one nor the other of these two forms of body predominates, and in this respect they contrast strongly with the other main classes (Scyphozoa and Anthozoa). Moreover, both polyp and medusa have a simpler plan of structure than in the other classes. The polyp itself is frequently (though not always) small. Its mouth leads directly into the internal cavity of its body (*coelenteron*), without the intermediary of a definite throat or gullet of any kind, and the ectoderm and endoderm (*see* COELENTERATA) meet at the lips. The coelenteron is a simple cavity lined by endoderm; it is not subdivided by partitions into lesser cavities, nor does it contain definite organs of any kind. With these limitations the actual form of the polyp varies very greatly. The medusa presents infinite variety of form, but it too lacks a throat, and although its coelenteron sends out radiating canals which run from the central cavity through the solid tissues of the bell, it is otherwise simple in that it contains no definite organs. The medusae of Hydrozoa are generally speaking smaller and more slightly-built creatures than the medusae belonging to the related class Scyphozoa, although in certain cases they attain a larger size than the average, which is a matter of millimetres. The Hydrozoa are also characterized by the fact that the sex-cells, when they ripen in the clusters known as *gonads*, typically lie in or under the ectoderm, although the site of their original formation may be in either ectoderm or endoderm.

It is among the Hydrozoa above all other Coelenterata that the phenomenon, briefly characterized elsewhere (article COELENTERATA), and known as *polymorphism*, attains its height. The details of this condition are described in parts of the present article and a summary of the question is given after the section on Siphonophora.

The infrequency of brackish or freshwater forms among the Coelenterata makes their occurrence of interest. The ordinary marine Hydrozoa are either pelagic (swimming or floating organ-

isms) or sedentary, according to their nature, and many of either kind exist. The brackish and freshwater forms exhibit the same diversity, though few in number. One of the most interesting is a minute creature, *Protohydra*, the length of which is about 3mm. This organism inhabits the surface-layer of mud, rich in diatoms, which is to be found in the bottom of pools in certain tidal marshes; it also occurs in oyster-beds and similar places. It is carnivorous, and reproduces freely by transverse fission, but its sexual mode of reproduction is unknown. It possesses no tentacles, and is as simple in structure as any known Coelenterate.

The best known of the non-marine Hydrozoa, however, are the genera *Limnocoelium*, *Limnocoelida*, *Cordylophora* and *Hydra*. Of *Hydra* more details are given below, and the chief interest of *Cordylophora* lies in the fact that it may flourish in water of different degrees of salinity as well as in fresh water; it is otherwise ordinary. *Limnocoelium ryderi* possesses a feebly developed polyp-generation (up to about 2mm. long) which produces small colonies containing about 2-7 individual polyps without tentacles. These colonies can produce buds of two kinds; some become separated from the parent, form polyps and produce new colonies, others develop into medusae, and these are liberated and swim away. The species of *Limnocoelium* (with which is now included *Microhydra*) are not very clearly recognized; but representatives of the genus occur in lakes, mill-streams and similar places in the United States, Germany, China and Japan, and have appeared in water-lily tanks at various botanic gardens, and in other tanks and aquaria. The genus *Limnocoelida* contains medusae which have been found in several river-systems in Africa and in some of the great lakes, as well as in India.

The Hydrozoa comprise three large orders which from this point onward will be treated separately.

ORDER I. HYDROIDA

The Hydroida are, roughly speaking, those Hydrozoa which possess a definite alternation of the polyp and the medusa in their life-history, and in which one generation (the polyp) is sedentary and usually constructs a fixed colony, the other being free-swimming when fully developed. There are various exceptions to this general statement, but they are not characteristic of the group as a whole. The variety of form and life-history exhibited, however, is so great, that it will need detailed treatment.

It is convenient to begin with the consideration of the common and well-known but quite untypical freshwater genus *Hydra* (fig.

1), which is the only thoroughly successful freshwater Coelenterate. *Hydra*, of one species or another, occurs in ponds and ditches and similar situations in many parts of the world. It consists of small isolated polyps, each with a pillar-like body and a limited number of tentacles. The length of the body is a matter of millimetres, and the tentacles in some species may be longer when stretched out than the body, although both they and the body can contract into rounded knobs. The *Hydra* attaches itself to stems and water-weeds, or floats beneath the surface film. It catches prey, often of a large size compared with its own bulk, in the manner characteristic of the Coelenterata (this is described in the article COELENTERATA) by stinging and then swallowing it. From the body of the *Hydra* there grow out buds, each of which acquires tentacles of its own and ultimately becomes separated from the parent; but no medusae whatever are produced, this being quite exceptional among the Hydroids. There are usually developed separately, on different parts of the body, ovaries and testes which give rise to the sex-cells. Whether this represents a degenerate condition, and there was once a medusa-stage in the life-cycle, or whether it is a primitively simple condition, cannot be determined.

The few other simple genera which are known, such as *Protohydra*, may be related to *Hydra*, or may be primitive or degenerate forms of separate origin. With the above preliminary, the characteristics of the group as a whole, without reference to these special forms, may be considered.

Structure.—The following is a description of the structure of a typical Hydroid, provided by the genus *Obelia* (fig. 2). *Obelia* begins its life, after the embryonic stages which succeed fertilization of the egg have transpired, as a single polyp, possessing a number of simple tentacles in a circlet around the base of its conical *peristome* or *manubrium*. The polyp sends out roots which attach it to the surface of a stone, the frond of a sea-weed, or other suitable support, and grows a stalk which raises it somewhat in the water. From this stem a bud arises from which, although it is at first a mere knob, a new polyp is gradually developed. This process of growth proceeds in a definite and regular manner, until a small tree-like colony, from less than an inch to several inches in height, is formed; the branches are definitely arranged, and all bear polyps. If one of the colonies be examined in detail, it will be found that each of the polyps possesses, outside its body, a little transparent cup of relatively stiff, horny material, into which it can withdraw when alarmed; and that not only are the polyps connected with each other by a stem composed of soft tissues, but the cups also are connected by a horny layer, outside the soft stem, which stiffens and supports the latter. The cups are known as *hydrothecae*, the soft stem as *coenosarc*, and the horny layer (including stem and cups) as the *perisarc*. The new polyps develop only from the tips of a branch of coenosarc, and not from one another; and in a well developed colony it will be seen that some additional branches have grown out, mostly in the lower part of the colony, each of them similar in structure to a developing polyp, and usually regarded as representing one. These branches (known as *blastostyles*) do not develop a mouth and tentacles; instead each produces a number of buds which gradually develop into small medusae, and which are known as *medusoid buds*. The blastostyle, like an ordinary polyp or *hydranth*, has a covering of perisarc

known as a *gonotheca*, but this is at first imperforate. In due course it becomes open at the end, and the medusae separate off from the blastostyle and swim away into the sea, where, after a period of free life, they become hydroid polyps.

FIG. 2.—OBELIA (ENLARGED) SHOWING PART OF A COLONY OF THE POLYP GENERATION AND ALSO A MEDUSA. THE COLONY BEARS BOTH ORDINARY POLYPS AND BLASTOSTYLES, THE LATTER PRODUCING MEDUSOID BUDS

The structure of one of these fully developed medusae must now be considered in more detail (fig. 3). The body has the form of an umbrella, with a manubrium similar to that of a polyp hanging down inside it and bearing the mouth at its end. The manubrium is lined by endoderm, and contains a cavity, the main part of the coelenteron. The substance of the umbrella consists of mesogloea with ectoderm on both external surfaces; but the layer of mesogloea is penetrated by four narrow tubes or canals, lined by endoderm, which run out from the base of the manubrium like the four arms of a cross. Connecting these *radial canals* with each other is a flat sheet of endoderm like a web (*endoderm lamella*) and also a *circular canal* which runs round the edge of the umbrella close to the bases of the tentacles. The latter are solid, both in medusa and polyp. At the edge of the bell, on the inner side of the ring of tentacles, is a little circular shelf (the *velum*) which projects inwards and slightly narrows the opening of the bell. Round the margin of the bell, at the bases of certain of the tentacles, lie the sense organs, minute sacs, formed by the ectoderm, and each containing a calcareous particle (the *statolith*). They are known as *statocysts* (fig. 5), and are eight in number, two being definitely placed in each of the quadrants between the radial canals; they probably initiate and control the swimming-contractions of the bell. The sex-cells of the medusa ripen in the ectoderm of four gonads which occur on the course of the four canals, and which, when ripe, shed their products into the sea. The fertilized eggs develop into new polyps

which initiate fresh colonies.

The story of *Obelia* is typical of the Hydroids, with modifications of one kind and another. In some cases the polyp-generation includes a single nutritive individual only, but usually it forms a colony. The form of the individual polyps and medusae, as also that of the colony, undergoes great modification however.

The polyps sometimes possess cups of perisarc as does *Obelia*; but often they are without these. Their tentacles are sometimes simple, sometimes knobbed at the tip or branched; sometimes arranged in one circlet, sometimes in two (one round the lip, one at the base of a conical manubrium), in other cases arranged irregularly over part or most of the surface of the polyp.

The medusae vary even more than the polyps, both in shape and structure, and some idea of the diversity which occurs among them may be gained by reference to figs. 2-4 and 7-8. The shape of the bell may be shallow or almost flat, or on the other hand may be a high dome, and naturally varies with the movements of the animal. The number, arrangement and structure of the tentacles is widely various. The living medusae are some of the most beautiful of marine creatures. Their transparency, which is often touched with definite colour in given parts, and the regularity of their structure are responsible for this, and in some cases their movements also are extremely graceful. The sense organs vary from one kind of medusa to another. Statocysts are present in a number of cases, and these exhibit varying degrees of complexity of structure, with this in common to all of them—that the epithelium of the statolithic sac or pit (for the simplest of statocysts consist of an open pit) is derived from the ectoderm, and no endoderm takes part in its formation. Many medusae possess sense-organs of another nature, known as *ocelli*, and these are sensitive to light. In their simplest condition they consist of a clump of sensory cells mingled with pigment cells; but the more complicated ones possess a definite lens. These ocelli may be situated close to statocysts, but many medusae possess ocelli only, and others statocysts only. Another important variation in structure is, that in some medusae, as in *Obelia*, the gonads are situated on the radial canals; but in many others the sex-cells ripen instead on the manubrium.

not constituting a really rigid skeleton. Many such colonies are an inch or less in height, although colonies several inches long are common. Only rarely does the colony become actually large, but in a few cases it achieves a size and solidity which give it rank with the reef-forming corals; in these cases the skeleton is massive and calcareous, and is in fact "coral."

Hydroid colonies are roughly speaking of two kinds—mat-like and tree-like structures. The mat-like forms consist of a network of rootlets, attached to a stone, sea-weed or other support, from the upper surface of which arise the polyps. The network is

FROM ALLMAN, "GYMNOBLASTIC HYDROIDS" (COUNCIL OF THE RAY SOCIETY)

FIG. 4.—MEDUSA OF CLADONEMA (ENLARGED)

This is an example of a jellyfish with branched tentacles. The gonads here form swellings on the manubrium; and the medusa adheres to surfaces through knobs on the basal branches of its tentacles

sometimes straggling, sometimes compact, and may form a continuous sheet. The tree-like forms are mostly delicate feathery structures, resembling rather the fronds of a finely divided seaweed than any animal. The general aspect of some of them is shown in the accompanying Plate. The size of the whole colony, the exact way in which it branches, and the way in which one polyp after another is added upon a branch, affect the general appearance of the ultimate result. Sometimes the branches themselves are thick and are composed of a dense network of branching rootlets (*Clathrozoön*, fig. 6), the polyps projecting at the surface. This condition, which is achieved in a manner different from that which produces the average tree-like colony, leads on to the state of affairs found in the massive, limy colonies.

These massive forms deserve special mention. They have been considered in time past as a separate group of Hydrozoa, the *Hydrocorallina*; but it has become evident that they are simply Hydroids with a more than usually solid skeleton, and that some of them are probably related to one series of Hydroid ancestors, others to a different series. A good example of these creatures is found in *Millepora* (see Plate). This animal constructs a colony containing innumerable minute individual polyps, which are connected with each other by a continuous surface-sheet of ectoderm and by a network of ramifying tubular rootlets. The colony secretes a massive, limy skeleton which may become a foot or more in height, and which is branched somewhat like the antlers of a stag, but in more compact fashion. The polyps inhabit little pits in the surface of the skeleton, and can retire into these completely when alarmed. The network of rootlets is lodged in a network of canals in the surface layers of the skeleton, the deeper parts consisting of coral only and containing no soft parts; this internal portion was secreted by the soft parts originally, but as growth proceeded and further skeleton was formed, these retired to the surface-layers. One can imagine that a similar state of affairs would be produced if a colony such as that of *Clathrozoön* were to secrete limy material into the meshes between its network of rootlets. *Millepora* is extraordinarily interesting in one

FROM KUKENTHAL, "HANDBUCH DER ZOOLOGIE" (DE GRUYTER)

FIG. 6.—PART OF A COLONY OF CLATHROZOON

respect. When the time comes for sexual medusae to be produced by the colony, these are not formed from buds as in *Obelia* and other Hydroids. Instead the sex-cells, which are migratory, move from the rootlets into one or other of the polyps. Each polyp so affected loses under their influence its characteristic structure, and becomes transformed by degrees into a medusa. The pit surrounding it enlarges and becomes closed in, so that it forms a cavity cut off from the outer world, and until the medusa is ready to escape it remains so; finally the cavity opens again and the medusa comes out. It is a weak swimmer and cannot feed; it swims a very little distance before shedding its ripe eggs or spermatozoa, the union of which gives rise to a polyp so that the life-cycle begins once more.

Diversities Exhibited by the Polyps and Medusae.—We may now pass on to some of the interesting diversities which the polyps and medusae exhibit. To begin with, in certain colonies, such as those of *Millepora* and *Hydractinia* (fig. 7), the hydranths are not all alike. Some of them (*gastrozooids*) possess mouths as well as tentacles, and inside these polyps digestion of food takes place. Other polyps on the contrary possess no mouths, but may have tentacles and are well provided with stinging capsules such as are described in the article COELENTERATA. These polyps themselves cannot feed, but they play a defensive part in the colony and assist the others in the capture and paralyzing of food; they are known as *dactylozooids*. This is a simple example of the phenomenon of polymorphism, which

has been previously mentioned and which will be further discussed later. It is carried to greater lengths in *Hydractinia* than in *Millepora*, since in this case the colony produces also *blastostyles* similar in principle to those of *Obelia*. These may be regarded as modified polyps with a body but without mouth or tentacles, which produce sexual buds. Therefore a *Hydractinia* colony possesses four kinds of individuals—gastrozooids, dactylozooids, blastostyles and sexual buds.

To turn to the medusae, we find here a most curious state of affairs. To begin with, medusae may arise from blastostyles or direct from ordinary polyps; and the blastostyles may arise from the root or stem of a colony or from a polyp itself. Moreover, a medusa may itself bud off others from its manubrium, or from its tentacle-bases or other parts. The most remarkable fact connected with the medusae, however, is that despite the fact that a medusa is obviously an advantageous development, in that it can swim away and spread the eggs and spermatozoa over an area vastly wider than they could otherwise reach, there is yet a strong tendency among the Hydroida towards a condition in which the medusa not only remains permanently attached to the colony whence it sprang, but also becomes much reduced and simplified in structure. A series of medusae can be traced, in which at one end there is found the fully formed free-swimming jellyfish, at the other end a degenerate sac-like structure, devoid of any medusa-like features, and resembling the gonad of an active medusa, such as that of *Obelia*. This degenerate formation, which remains attached to the colony, is known as a *sporosac*, and consists of a layer of ectoderm containing or covering the sex-cells, and surrounding an endodermal core. Between these two extremes all intermediate stages may be found.

It has been considered by some authors that the sporosacs represent, not a reduced but a primitive condition, and that the other stages are to be regarded as developments leading up to

medusae; the gain being increased fertility.

The Coelenterata are singularly free from parasitic members. Of the few that are known, one is particularly interesting. This *Hydrichthys boycei*, a species referred to the Hydroida but which may be an unusual siphonophore. The colony is one of the mat-like kind, and the mat, instead of being affixed to a stone or weed, is attached to the fins or body of a fish. The underside of it sends

the fully formed medusa. This would seem reasonable from the point of view that the roving medusa is an obvious gain to a fixed colony; but the facts of the case do not seem to support it. From the structure and mode of occurrence of the various grades of medusae, and from the fact that in the development of certain of the reduced forms, medusoid features appear for a time and are subsequently lost, it is judged that they are not primitive but degenerate. The precocious development of the sex-cells may be the factor which leads to the reduction of the

roots into the integuments of the fish, and under its growing edge are cells which are able to destroy the surface of the fish's skin and expose the vascular layer beneath. The polyps, which have no tentacles, bend down over the edge of the mat, apply their mouths to the wound made by the latter, and obtain blood from the vessels of the fish. Another parasite, better known than *Hydrichthys*, is *Polypodium*; this is parasitic at one stage of its life in the eggs of a sturgeon, which it destroys.

Classification.—The classification of the Hydroida is instructive, though as yet imperfect. The connection between medusae and polyps was at first not understood by naturalists, since it could not be deduced from observation of one of these types only, without a study of the whole life-history. Even now there are polyps and medusae which have not yet been linked on to their corresponding alternative form. Consequently a double classification has grown up, dealing with the two sets independently, and the two systems can be correlated with each other so far as the inter-connections are known.

The polyps are divided into:—

1. *Gymnoblastera*. Here the polyps are not enclosed in cups of perisarc (hydrothecae), nor are the blastostyles enclosed in gonothecae.
2. *Calyptoblastera*. Here the polyps possess hydrothecae and the blastostyles gonothecae.

The medusae are classified as follows:—

1. *Anthomedusae*. Medusae in which there are no statocysts (though there are usually ocelli) and in which the gonads develop on the manubrium. These are the medusae belonging to the *Gymnoblastera* polyp-generation.
2. *Leptomedusae*. Medusae in which there are typically statocysts and sometimes ocelli, and in which the gonads are arranged on the radial canals. These medusae belong to the *Calyptoblastera* polyp-generation.

In the above scheme *Hydra* and its relatives would be considered *Gymnoblastera* by some authors, by others they would be placed in an independent group, the *Hydrida*. The affinities of *Limnocoelium* and *Limnocoelida* are somewhat uncertain.

2. Millepora, a hydroid coral, bearing the polyps in minute tubular pits in the hard calcareous skeleton
3. Colonies of Pennaria, showing polyps borne on small lateral branches
4. Colonies of Obelia, showing complex tree like branching

ORDER II. TRACHYLINA

The Trachylina are an assemblage of Hydrozoa which differ sufficiently from any of the Hydroida or Siphonophora to warrant their inclusion in a separate group.

Among the Trachylina the medusa is the dominant form, and many reach a considerable size (e.g., 10 x 3 cm.). In accordance with this fact the Trachylina are mostly oceanic forms, pelagic throughout life; whilst the Hydroida are tethered, so far as their polyp-generation is concerned, to the bottom or to sea-weed, and include many characteristic shore-forms. The cleavage of the fertilized egg of the Trachylina typically produces a planula (see COELENTERATA), which develops into a more or less distinctly polyp-like larva; the latter is transformed directly into a medusa (fig. 8). In certain forms (Cuninidae) the polyp-larva is parasitic within medusae of its own or other kinds. In such cases it reproduces by budding, and both the parent and daughter polyps become transformed into medusae; or, the larva may form a stolon from which medusae are budded.

Beyond the facts thus outlined the Trachylina contribute little of general interest to the study of the Coelenterata, although their structure and life-histories are in themselves extremely interesting. For this reason they are dealt with very briefly here, and the only part of their structure calling for further mention is that of the sense organs. Ocelli (eye-spots) are rare amongst them, but all possess organs containing statoliths. These are of a different grade from those of the Hydroida, in that they exhibit the structure, not of ectodermal pits or sacs containing statoliths, but of small tentacles containing an endodermal core in which lie one or more statoliths, and covered by ectoderm. These modified tentacles are known as *tentaculocysts* (fig. 9), and they may, like tentacles, project freely at the surface, or may themselves become embedded in a pit or sac formed by the surrounding tissues.

ORDER III. SIPHONOPHORA

The Siphonophora constitute one of the most interesting groups of the animal kingdom, since they illustrate the lengths to which an organism may go in the direction of stringing together a number of different kinds of individuals in a single chain. In scientific terminology they exhibit at its height the phenomenon of polymorphism.

The Siphonophora, unlike the Hydroida, are essentially pelagic animals: they are exclusively marine, and most characteristic of warm seas. They one and all form colonies, but the colony is unattached and either floats or swims. It produces sexual medusae comparable to those of a hydroid, and these may or may not be set free from the colony; consequently there may be an alternation of generations, both pelagic, or the medusa-generation may never gain independent existence. There is however this difference from the state of affairs among the Hydroida, that a medusa which is set free as such is an exception, and that it has never the full structure of a Hydroid medusa, possessing no mouth or sense-organs. Most siphonophore medusae remain attached to the colony or to a segment of it, and many of them exhibit grades of reduction in structure. These are known as *gonophores*, but they are never as degenerate as a Hydroid sporosac. From the eggs produced by the medusae or gonophores a planula larva of a curious type develops, and this by budding produces a colony. The siphonophore contrasts with a trachylina in that it is here the colony, and not the sexual medusa, which is the dominant form; and in addition to this a new factor is introduced which is not found either in the Trachylina or in the Hydroida. This is the production by the colony not only of more than one kind of polyp (as in *Hydractinia*) but also

FROM DELAGE AND HEROUARD, "ZOOLOGIE CONCRÈTE" (REINWALD) (COPR. BONNAIRE)

FIG. 10.—THE STRUCTURE OF A STRING-LIKE SIPHONOPHORE COLONY. FIG. 11.—TYPES OF INDIVIDUALS TO BE FOUND IN A TYPICAL SIPHONOPHORE CLUSTER

B, bract; C, coenosarc; CO, oormidium; D, dactylozoid; F, float; FL, tentacle of gastrozoid; G, bunch of gonophores; GZ, gastrozoid; NB, battery of sting cells; S, swimming-bell; T, tentacle of dactylozoid

of more than one kind of medusa. In addition to the sexual medusae corresponding to the sole medusa-form in the other groups, there are found here medusae of modified structure which neither feed nor produce gonads, but which act as swimming-bells for the whole colony; and other structures which are also probably modified medusae. Of these latter one is a medusa transformed into a gas-containing float.

Structure of Colonies.—It will be impossible to understand or to visualize the siphonophore organization, without first con-

sidering the structure of several typical colonies; these are so diverse in constitution that a general statement at the present stage would be unprofitable.

The first colony to be described will be that of *Halistemma* (figs. 10 and 11). At the upper end of this lies a small float, and depending from it a long thin string which is tubular and contractile. This is the *coenosarc* and corresponds to the stalk of an *Obelia*. Arranged on the string just below the float are a number of swimming-bells; each of these is a medusa attached to the coenosarc by a short stem arising from the outer side of its bell, and possessing radial canals and a velum but no manubrium or mouth. At intervals along the coenosarc are found little knots or clusters of individuals. These are not all alike, larger and smaller ones alternating regularly. Each cluster (*cormidium*) contains a certain number of individuals, but not the same selection in each case. The types of individuals comprised in the whole series are leaf-like protective structures, the *bracts*, together with digestive polyps (*gastrozooids*) each with a mouth and with a single tentacle which is attached to it at the base; other polyps (*dactylozooids*) with no mouths, each with a single tentacle at its base, which act as feelers and stingers; and lastly *blastostyles* upon which male and female gonophores are produced. The tentacles of the gastrozooids, which act as fishing-lines, are branched, the branches bearing terminal stinging-batteries; those of the dactylozooids are unbranched.

A type of colony similar in principle to that of *Halistemma* is formed by *Physophora*. Here we begin as before with a small float bearing a tubular string of coenosarc with swimming-bells. But below these bells, the rest of the coenosarc, instead of forming a long string, is short and compact, with the result that all the other individuals of the colony (which include dactylozooids, gastrozooids and blastostyles) are concentrated into a group with the dactylozooids forming a protective circlet round the outside. The same principle is further exemplified in a still more modified degree by *Stephalia* (fig. 12), in which the same essentials are present but the proportions and shapes of all the parts have changed. In this case the float is large and prominent and it opens to the exterior through a special spout-like structure (*aurophore*) at one side. The swimming-bells are restricted to a single circle below the float, instead of being strung out as in *Halistemma* and *Physophora*, and the coenosarc bearing the cormidia is neither the long string of the former nor the insignificant vesicle to which it is reduced in the latter, but is a bulky mass bearing in the middle of its lower surface a large terminal gastrozooid, and supporting the cormidia on its sides. This mass is penetrated by a number of tubes lined by endoderm, which run into each other and communicate with the digestive cavities of the gastrozooids.

From *Stephalia* to *Physalia* (fig. 13) is a natural transition. Here there are no longer any swimming-bells, but there is a large crested float opening to the outside by a pore, and bearing a gastrozooid at one end. In a young *Physalia* the underside of the float bears directly half a dozen cormidia, each containing a gastrozooid without a tentacle, a dactylozooid with a long unbranched fishing-line, and a branching blastostyle bearing small dactylozooids upon it, and also male and female gonophores. As the colony increases in size new individuals are added somewhat irregularly upon the stalks of the old, and the simple early arrangement is lost. The colours of *Physalia* (blue, orange, etc.) are of great brilliance, and it is a well-known denizen of the Atlantic, Pacific and Indian Oceans, often occurring in fleets, and commonly known as "Portuguese Man-of-War." One of its fishing-lines reaches a greater length than all the others, attaining more than a yard; and the stinging powers of these lines are

extremely powerful, producing serious conditions after contact with them even in man. The colony is not bound to float at the surface; it can deflate the float and sink, reforming the gas within it and so rising once more, within a quarter of an hour.

A colony quite unlike any so far described is formed by *Velella*. Here the whole organism has the aspect at first sight of a single flat medusa bearing a sail on its upper side and tentacles round

FROM DELAGE AND HEROUARD, "ZOOLOGIE CONCRETE" (REINWALD) (COPR. BONNAIRE)

FIG. 13.—DIAGRAM OF A YOUNG COLONY OF PHYSALIA

The swimming-bells are restricted to a single circle and not strung out as in *Halistemma* and *Physophora*

its margin (fig. 14). On closer examination it is found, however, that the apparent tentacles are really a circle of long dactylozooids, and that the underside of the disc-like colony is covered by a number of curious blastostyles which, unlike an average blastostyle, possess mouths. In the centre of these is a single large gastrozooid, the only one which the colony possesses. The disc-like portion of the animal to which all these polyps are attached is complex in structure. It is thick and contains below the skin-layers of its upper side an internal horny float, below which is a mass of soft tissue, a concentrated coenosarc. The float is itself flattened in shape, is subdivided into chambers, bears a vertical extension in the centre stiffening the "sail," and is prolonged into the soft tissues as fine *air-tubes*. The coenosarc contains a ramifying system of endodermal tubules, in communication with the cavities of the various polyps, which is probably both absorptive and excretory in function. The coenosarc also contains a massive concentration of nematocysts, doubtless a nursery whence they migrate when sufficiently developed into the parts where they can function. Very similar to *Velella* but without a sail, is *Porpita*. In these creatures we have reached a stage in which the colony has become so compact and the parts so markedly subordinated to the whole that their interrelation resembles rather that of organs than that of independent beings; but free medusae are liberated by the colony.

Finally it may be mentioned that there are a number of siphonophore colonies which differ from any so far mentioned in that they possess swimming-bells but no float.

We may now summarize the state of affairs in this very curious group of animals. In the course of the above descriptions mention has been made of a number of structures—gastrozooids, blastostyles, dactylozooids; swimming-bells, floats, bracts; and sexual medusae (fig. 11). It remains to comment on the status of these various entities. Continuing the view which is taken throughout the articles on Coelenterata in this Encyclopædia, most or all of these structures represent individuals, modifications

of either the polyp or the medusa form of body, or independently developed entities of equivalent standing. The gastrozooids and dactylozooids are varieties of polyp, the sexual medusae, the swimming-bells, and probably the bracts are modifications of medusae. The float is sometimes regarded as the invaginated upper end of the stem of coenosarc, and sometimes as a modification of a medusa. The status of the blastostyles is uncertain; they represent polyps in *Velella*, in other cases they are perhaps the present day substitute for bygone polyps.

It should be mentioned in conclusion that the Siphonophore is regarded by Moser not as a colony of individuals but as an individual animal with division of labour between organs and "on the way to alternation of generations and to colony-formation"; and that the medusae of *Velella* are regarded by this author as free-swimming gonophores leading up to true sexual medusae. The work of Moser has thrown considerable light on the morphology and the development of the Siphonophora, and has made clearer than formerly the homologies of parts throughout the group, especially that of the float, which may fairly be regarded as equivalent to the apical adult bell of the forms with no float. This work also forms a valuable contribution to the question of evolution within the Siphonophora, but in the view of the present writer it hardly establishes the claim that a siphonophore is an individual animal (see also the following section on Polymorphism).

POLYMORPHISM

In the articles COELENTERATA and ANTHOZOA, and in accounts of the groups of Hydrozoa already dealt with in the present article, references will be found to the phenomena known as *polymorphism* and *alternation of generations* (*metagenesis*). Since these phenomena are aspects of one and the same thing, and are of general interest and importance, a summary of the subject is indicated. In the following remarks it is taken for granted that the articles above mentioned are familiar to the reader.

Firstly it must be made clear that alternation of generations as found in *Obelia* is simply an example of polymorphism, which may be defined as the ability of a single species of animal to exist under more than one form—in this instance as polyp and medusa. In a clear-cut case of alternation of generations one of these forms is sexual and *succeeds* the alternative non-sexual form, the two

non-sexual as well as sexual medusae, and probably more than one kind of these (swimming-bells, bracts and float).

In other words there exists (a) a differentiation into sexual and non-sexual forms and (b) a division of labour between the non-sexual forms by virtue of which they become, for practical purposes, reduced to the condition of organs.

It must be noted however that the sexual forms tend to lose their independence; and the separate free-swimming generation so obvious in *Obelia* and similar forms becomes at the other end of the series a degenerate sporosac attached to the colony as permanently as any non-sexual individual. In fact it has become a sex-organ or gonad, and "alternation of generations" has been transformed into "division of labour."

Interesting divergences from the ordinary kinds of polymorphism typical of the Hydroida and Siphonophora are found among the Trachylina, Scyphozoa, and in forms such as *Millepora*. In *Millepora* a polyp, be it a gastrozooid or a dactylozooid, becomes directly transformed under the influence of the immigrating sex-cells into a medusa, instead of the medusa being formed from an independent bud. The polyp is a changeling. In the Trachylina the same process takes place, but in this case it is a pelagic or parasitic larval polyp which turns into a jellyfish, not an adult member of a colony. Among the Scyphozoa a unique condition exists; here the alternation of generations is very marked, and the medusa arises from the polyp direct; but in this case the polyp divides itself transversely into a series of superimposed saucer-like sections, which separate from it one by one, each becoming a medusa. A single polyp has therefore produced not one but several medusae. This is partly paralleled by a blastostyle, for if the latter be a polyp it produces by *budding*, several medusae; but the scyphozoan polyp achieves the same end quite differently.

The Anthozoa are the least interesting of the Coelenterata from the point of view of polymorphism. They possess no medusoid form and among their polyps little polymorphic variation in form occurs. In certain colonial forms ordinary polyps and siphonozooids co-exist, and there is also a distinction in some colonies between an original axial polyp and those subsequently formed. In the coral *Fungia* part of the life-cycle in some respects resembles the strobilization of the Scyphozoa.

Polymorphism is chiefly interesting as an example of the extraordinary ability of animals to produce an almost infinite number of variations upon a given theme. It has also been much employed as a subject for argument, however, and it should be mentioned here that the viewpoint regarding it which has been adopted in all the articles on Coelenterata in this Encyclopædia is not universally accepted. The argument here adopted has been that a siphonophore or a compound Hydroid is a *colony* and that its parts represent, morphologically speaking, *individuals* connected by a common intermediate tissue, the coenosarc. This view may appear to be far-fetched when one contemplates a sporosac, which is in effect a gonad, since it involves the claim that this structure represents not an organ but an animal. It is also true that in some cases, such as those of meandrine corals, it is difficult to decide whether a polyp with a dozen mouths represents one polyp or twelve. But taking the whole story, as presented to us throughout the Coelenterate series, as a unity, the interpretation of the systems encountered as colonies of individuals appears to be the soundest working hypothesis. The alternative view, that everything which results from the development of a single egg is an individual animal, however much it may subdivide asexually, and that gastrozooids, bracts, and the rest are nothing more than the organs of this animal, seems relatively satisfactory when applied to such a form as the adult *Velella*. But when one applies it to a free-swimming medusa it becomes reduced to an absurdity—is a jellyfish, an organism provided with mouth and stomach, canals, velum, tentacles and sense-organs, simply a moving *organ* and not an animal at all? Further, one may meet on many shores hosts of sea anemones, none of which have developed from eggs—each is an independent organism, not part of a colony, and each has been produced asexually by fission. Are these anemones then "organs"? To reduce the term "organ" to such a level is to remove its actual meaning. It is interesting to note that Moser

FROM DELAGE AND HEROUARD, "ZOOLOGIE CONCRÈTE" (REINWALD) (BONNAIRE)

FIG. 14.—DIAGRAM ILLUSTRATING THE STRUCTURE OF VELELLA
A sector of the disc-shaped coenosarc has been cut away so as to reveal the internal structure

co-existing on a single colony only for the period during which the medusae are developing from buds.

The other type of polymorphism is that which is exhibited by such colonies as *Hydractinia* and in far higher degree by the Siphonophora, and in which there is not only the distinction of individuals into sexual and non-sexual forms, but the non-sexual polyps are themselves divided into kinds (gastrozooids, dactylozooids, etc.). This is exemplified even in *Obelia* by the distinction of the polyps into hydranths and blastostyles. In the Siphonophora there is the additional development that here there exist

combines the two theories by regarding the Coelenterata other than Siphonophora as colonies of individuals, but the Siphonophora themselves as relatively primitive organisms, individuals comprising organs and the fore-runners of true colonies.

In this connection it should however be noted that in the above paragraphs the term "individual" has been used in a purely morphological sense—i.e., the individuals of a Siphonophore represent morphological individuals which have suffered a loss of independence similar to that of the component cells of any multicellular animal, which latter may be regarded as having been derived originally from a colony of individual single-celled animals (protozoa). In a physiological sense on the other hand the Siphonophore colony is a unity and may be regarded as an individual system. The status of such a system in relation to the wide general question of individuality is further discussed in the article on that subject.

HYENA, the name applied to members of the family *Hyaenidae*, a group of Carnivora (*q.v.*) distinguished by the four toes on each foot, the comparative length of the forelegs, the non-retractile claws, and the enormous strength of the jaws and teeth, enabling them to crush hard bones. Three species are known, belonging to the genus *Hyaena*.

The striped hyena (*H. striata*) has the widest distribution, being found in India, Persia, Asia Minor, North and East Africa. About the size of a wolf, the animal is greyish-brown in colour, marked with indistinct longitudinal stripes of a darker hue. There is a mane along the neck and back. The animal is nocturnal in habits and has an unearthly cry, aptly compared to demoniac laughter. It feeds mainly on carrion, but occasionally carries off sheep, goats and dogs. It is a solitary and cowardly animal.

The spotted form (*H. crocuta*) ranges from Abyssinia to the Cape, and is yellowish-brown, with darker spots. The brown hyena (*H. brunnea*) is South African, and about the size of the striped species. It is ashy brown in colour, with a lighter collar, chest and belly. Both spotted and striped hyenas have been found fossilized in the Pliocene of Europe.

HYÈRES, a town in the department of the Var in S.E. France, 11 m. by rail E. of Toulon. Pop. (1926) 11,697. The town of Hyères was founded in the 10th century, as a place of defence against pirates, and takes its name from the *aires* (*hierbo* in the Provençal dialect), or threshing-floors for corn, which then occupied its site. It passed from the possession of the viscounts of Marseille to Charles of Anjou, count of Provence. The château on the summit of the hill was dismantled by Henri IV., but the town resisted in 1707 an attack made by the duke of Savoy. Hyères is celebrated (as is also its fashionable suburb, Costebelle, nearer the seashore) as a winter health resort. The town is situated about 2½ m. from the seashore on the sheltered south-western slope of a steep hill (669 ft. of the Maurettes chain) but is exposed to the Mistral. To the south-west, across a narrow valley, is the suburb of Costebelle. The older portion of the town is surrounded, on the north and east, by remnants of its mediaeval walls, and has steep and dirty streets. The more modern quarter has broad boulevards and villas, with gardens, filled with semi-tropical plants. The parish church of St. Louis was built originally in the 13th century by Franciscan friars, and restored in the 19th century. The plain between the new town and the sea has large nurseries, an excellent *jardin d'acclimatation* and many market gardens, which supply Paris and London with early fruits and vegetables, especially artichokes and roses in winter.

HYGIEIA, in Greek mythology, the goddess of health. The oldest traces of her cult, so far as is known at present, are to be found at Titane in the territory of Sicyon, where she was worshipped together with Asclepius, to whom she appears completely assimilated, not an independent personality. Her cult was not

introduced at Epidaurus till a late date, and therefore, when in 420 B.C. the worship of Asclepius was introduced at Athens coupled with that of Hygieia, it is not to be inferred that she accompanied him from Epidaurus, or that she is a Peloponnesian importation at all, but rather a new invention, an offshoot of the already existing worship of Athena Hygieia. At first no special relationship existed between Asclepius and Hygieia, but grad-

VOTIVE RELIEF FOR AN AESCULAPIUM, OR TEMPLE OF AESCULAPIUS; GREEK SCHOOL, EARLY 4TH CENTURY, B.C.; ORIGINAL IN NATIONAL MUSEUM AT ATHENS

ually she came to be regarded as his daughter, the place of his wife being already secured by Epione. Later Orphic hymns, however, and Herodas, iv. 1-9, make her the wife of Asclepius. The cult of Hygieia then spread concurrently with that of Asclepius, and was introduced at Rome from Epidaurus in 293, when she was gradually identified with Salus (*q.v.*). While in classical time Asclepius and Hygieia are simply the god and goddess of health, in the declining years of paganism they are protecting divinities.

See H. Lechat in Daremberg and Saglio's *Dictionnaire des antiquités*, with full reference to authorities; and E. Thrämer in Roscher's *Lexikon der Mythologie*.

HYGIENE, the science of preserving health. The subject embraces all agencies affecting the physical and mental well-being of man, and requires acquaintance with physics, chemistry, geology, engineering, architecture, meteorology, epidemiology, bacteriology and statistics. On the personal side it involves consideration of food, water and other beverages; clothing; work, exercise and sleep; personal cleanliness, special habits, such as the use of tobacco, narcotics, etc.; and control of sexual and other passions. In its public aspect it deals with climate; soil; character, materials and arrangement of dwellings; heating and ventilation; removal of excreta and other waste matters; medical knowledge on incidence and prevention of disease; and disposal of the dead.

These topics will be found treated in such articles as ADULTERATION, BACTERIOLOGY, CREMATION, DIET AND DIETETICS, FOOD, FOOD-PRESERVATION, HEATING, HOUSING, INDUSTRIAL WELFARE AND MEDICINE, MENTAL HYGIENE, SOCIAL HYGIENE, SEWER CONSTRUCTION, VENTILATION, WATER, etc. For general principles governing the sanitary well-being of the community see PUBLIC HEALTH and PREVENTIVE MEDICINE.

HYGINUS (d. c. 140), eighth pope. It was during his pontificate (c. 137-140) that the gnostic heresies began to appear in Rome.

See *Liber Pontificalis* ed. Duchesne.

HYGINUS (surnamed GROMATICUS, from *gruma*, a surveyor's measuring-rod), Latin writer on land-surveying, flourished in the reign of Trajan (A.D. 98–117). Fragments of a work on legal boundaries attributed to him will be found in C. F. Lachmann, *Gromatici Veteres*, i. (1848).

A treatise on Castrametation (*De Munitionibus Castrorum*), also attributed to him, is probably of later date, about the 3rd century A.D. (ed. W. Gemoll, 1879; A. von Domaszewski, 1887).

HYGINUS, GAIUS IULIUS, Latin author, a native of Spain (or Alexandria), was a pupil of the famous Cornelius Alexander Polyhistor and a freedman of Augustus, by whom he was made superintendent of the Palatine library (Suetonius, *De Grammaticis*, 20). His numerous works included topographical and biographical treatises, commentaries on Helvius Cinna and the poems of Virgil, and disquisitions on agriculture and bee-keeping. All these are lost.

Under the name of Hyginus there are extant: (1) *Fabularum Liber*, some 300 mythological legends and celestial genealogies, valuable for the use made by the author of the works of Greek tragedians now lost; (2) *De Astronomia*, usually called *Poetica Astronomica*, containing an elementary treatise on astronomy and the myths connected with the stars, chiefly based on Eratosthenes. Both are abridgments and both are by the same hand; but the style and the elementary mistakes (especially in the rendering of the Greek originals) are held to prove that they cannot have been the work of so distinguished a scholar as Hyginus. It is suggested that they are an abridgment (made in the latter half of the 2nd century) of the *Genealogiae* of Hyginus by an unknown grammarian, who added a complete treatise on mythology.

EDITIONS:—*Fabulae*, by M. Schmidt (1872); *De Astronomia*, by B. Bunte (1875); see also Bunte, *De C. Iulii Hygin, Augusti Liberti, Vita et Scriptis* (1826).

HYGROMETER, an instrument for determining the humidity of the atmosphere (Gr. *ὕγρὸς*, wet, *μέτρον*, a measure), an instrument which determines the humidity changes only is termed a "hygroscope." The earlier instruments generally depended for their action on the alterations in the length of substances when exposed to varying degrees of moisture; catgut, twisted cords and wooden laths, all of which contract with an increase in the humidity, being the most frequently employed.

Many of the early forms are described in C. Hutton, *Math. and Phil. Dictionary* (1815). Modern instruments, which utilize other principles, are described in METEOROLOGY.

HYKSOS or "SHEPHERD KINGS," the name of the earliest invaders of Egypt. Josephus (*c. Apion.* i. 14), who identifies the Hyksos with the Israelites, preserves an account of them from bk. ii. of Manetho. According to it, in the days of King Timaeus, Egypt was invaded from the east by a destructive band who elected a king named Salatis. He made all Egypt tributary and established garrisons and fortresses in various parts of the country. His successors Beon, Apachnas, Apophis, Jannas and Asses reigned c. 199 years, and all aimed at extirpating the Egyptians. Their race was named Hyksos, i.e., "shepherd kings," and some say they were Arabs (another explanation found by Josephus is "captive shepherds"). When their successors had held Egypt for 511 years, a rebellion began at Thebes. Misphragmuthosis confined the "Shepherds" in Avaris; and his son Thutmosis, failing to capture the stronghold, allowed them to depart; whereupon they established themselves, 240,000 in number, in Judea and built Jerusalem.

In Manetho's list of kings, the six above named form the 15th dynasty, and are called "six foreign Phoenician kings." The 16th dynasty is made up of thirty-two "Hellenic shepherd kings," the 17th is of "shepherds and Theban kings" (reigning simultaneously). The lists vary greatly in different versions, but the above seems the most reasonable selection of readings. For "Hellenic" see below. In 1847 E. de Rougé proved from a papyrus of the British Museum, that Apopi was one of the latest of the Hyksos kings, corresponding to Aphobis; he was king of the "pest" and suppressed the worship of the Egyptian gods in favour of his god Setekh or Seti.

In 1850 a record of the capture of Hawari (Avaris) from the

Hyksos by Ahmosi, founder of the 18th dynasty, was discovered by the same scholar. A large class of monuments was afterwards attributed to the Hyksos. Some statues, found in 1861 by Mariette at Tanis, had peculiar "un-Egyptian" features. One of these bore the name of Apopi engraved lightly on the shoulder, and on other grounds it was concluded that the features were those of the Hyksos. In 1893 Golenischeff produced an inferior example bearing its original name, which showed that it represented Amenemhe III. In consequence it is now generally believed that they all belong to the 12th dynasty. Meanwhile a headless statue of a king named Khyan, found at Bubastis, was attributed to the Hyksos, the soundest arguments being his foreign name and the boastful un-Egyptian epithet "beloved of his ka." His name was afterwards recognized on a lion found in Baghdad. Flinders Petrie then pointed out a group of kings named on scarabs of peculiar type, which, including Khyan, he attributed to the period between the Old Kingdom and the New, while others were in favour of assigning them all to the Hyksos, whose appellation seemed to be recognizable in the title Hek-khos, "ruler of the barbarians," borne by Khyan.

Besides the histories of Egypt, see J. H. Breasted, *Ancient Records of Egypt*; Historical Documents ii. 4, 125; G. Maspero, *Contes populaires*, 3me éd.; W. M. F. Petrie, *Hyksos and Israelite Cities*.

HYLAS, in Greek legend, son of Theiodamas, king of the Dryopians in Thessaly, the favourite of Hercules and his companion on the Argonautic expedition. Having gone ashore at Kios in Mysia to fetch water, he was carried off by the nymphs of the spring in which he dipped his pitcher. Hercules sought him in vain; and ever afterwards, in memory of the threat of Hercules to ravage the land if Hylas were not found, the inhabitants of Kios every year on a stated day roamed the mountains, shouting aloud for Hylas. (so Apollonius Rhodius I. 1207 et seq., and later authors). But, although the legend is first told in Alexandrian times, the "cry of Hylas" occurs long before as the "Mysian cry" in Aeschylus (*Persae*, 1054); and in Aristophanes (*Plutus*, 1127) "to cry Hylas" is used proverbially of seeking something in vain.

HYLOZOISM, in philosophy, a term applied to any system which explains all life, whether physical or mental, as ultimately derived from matter ("cosmic matter," *Weldstoff*) (Gr. *ὕλη* matter, *ζωή*, life.) Such a view of existence has been common throughout the history of thought, and especially among physical scientists. Thus the Ionian school of philosophy, which began with Thales, sought for the beginning of all things in various material substances, water, air, fire (see IONIAN SCHOOL). These substances were regarded as being in some sense alive, and taking some active part in the development of being. This primitive hylozoism reappeared in modified forms in mediaeval and Renaissance thought, and in modern times the doctrine of materialistic monism is its representative.

HYMANS, PAUL (1865–), Belgian statesman, was born at Ixelles, Brussels, on March 23, 1865. He became a barrister in 1885, and from 1898 to 1914 was professor of comparative parliamentary history at Brussels university. From 1900 he was deputy for Brussels and soon became the Liberal leader. After a mission to President Wilson in Aug. 1914 he was plenipotentiary in London, 1915–17, when he became head of the ministry of economic affairs. From 1918–20 and 1924–25 he was minister for foreign affairs. In Nov. 1918 he attended the inter-Allied Council at Versailles; he also represented Belgium at the Peace Conference in 1919 and on her behalf signed the peace treaty. In the same capacity he attended the conferences at San Remo, Boulogne, Brussels and Spa. He played a leading part in the settlement of the Ruhr question, the Dawes Plan, the Security Pact and the economic union of Luxembourg with Belgium. In Jan. 1920 he was appointed Belgian representative on the League of Nations, and in the same year was made president of the first Assembly at Geneva. On Nov. 29, 1927 he became minister of foreign affairs again after the reconstruction of the Jaspas cabinet. A member of the Académie Royale de Belgique, Hymans continued *L'histoire parlementaire de la Belgique* (1875, etc.) and wrote *Frère-Orban* (1905, etc.) and *Portraits, essais et*

discours (1914).

HYMEN or **HYMENAEUS**, originally the refrain of the song sung at marriages among the Greeks. As usual, the name gradually produced the idea of an actual person whose adventures gave rise to the custom of this song. He occurs often in association with Linus and Ialemus, who represent similar personifications, and is generally called a son of Apollo and a Muse. As the son of Dionysus and Aphrodite, he was regarded as a god of fruitfulness. In Attic legend he was a beautiful youth who, being in love with a girl, followed her in a procession to Eleusis disguised as a woman, and saved the whole band from pirates. As reward he obtained the girl in marriage, and his happy married life caused him ever afterwards to be invoked in marriage songs (Servius on Virgil, *Aen.* i. 651).

See J. A. Hild in Daremberg and Saglio's *Dictionnaire des antiquités*.

HYMENOPTERA, the term used in zoological classification for that order of insects comprising ants, bees, wasps, and their allies the saw-flies, gall-wasps and ichneumon flies. These insects all exhibit the following characters: (1) The presence of two pairs of stiff membranous wings often with the venation reduced

the perfection of their structure but also with regard to the remarkable development of their instincts. In the latter respect they stand at the head of all invertebrate animals and their behaviour has been the subject of studies by many of the most famous naturalists. About 60,000 species are known but many thousands more still await discovery and even in the British Isles it is only the ants, bees and wasps that have been adequately collected and

FROM MARLATT, "ENTOMOLOGICAL BULLETIN," U.S. DEPT. OF AGRIC.

FIG. 1.—HYMENOPTERA: MOUTH PARTS OF SAW-FLY (*PACHYNEMATUS*) These are used principally for feeding, but in the bee the ligula is modified for sucking nectar

or almost absent: the hind-wings are smaller than the fore-pair and are interlocked with them by tiny hooklets. (2) The mouth-parts have biting jaws, but the labium is usually modified into a kind of tongue for lapping or sucking. (3) The abdomen is generally constricted at the base to form a waist and its first segment is joined up with the thorax: an ovipositor is present and used for sawing, piercing or stinging. (4) Metamorphosis is complete and the larvae are either caterpillars or more often vermiform: the pupae are usually in cocoons and their appendages are free.

Hymenoptera form one of the largest and most highly developed orders of insects and are of great interest, not only on account of

AFTER IMMS, "GENERAL TEXT BOOK OF ENTOMOLOGY"

FIG. 2.—LATERAL VIEW OF THE THORAX AND BASE OF ABDOMEN OF HONEY BEE

The thorax is chiefly characterized by its fusion with the first segment of the abdomen. The parts of the pre- and metathorax are shaded; mesothorax and abdomen are plain

studied. Although the vast number of species are solitary like other insects, individuals of some species have acquired the habit of living together in great societies as is the case in ants, and certain bees and wasps: their social life and behaviour is fully discussed in the article *SOCIAL INSECTS*. Hymenoptera are also remarkable for the highly evolved condition parasitism has reached in the order: tens of thousands of species betray this habit, and although they confer immense benefit to man as agents destroying other forms of insect life, they have been relatively little collected, and in many parts of the world are quite unstudied.

General Structure.—Hymenoptera have acute vision, the compound eyes are consequently large and there are usually three ocelli or simple eyes. The antennae are often very different in the two sexes and in the bees and wasps they are generally composed

FROM SNODGRASS, "ANATOMY OF THE HONEY BEE," U.S. DEPT. OF AGRIC.

FIG. 3.—SEMI-DIAGRAMMATIC VIEW OF LEFT SIDE OF STING OF WORKER HONEY BEE

of 13 joints in the males and 12 joints in the females. The mouth-parts exhibit their simplest form in saw-flies (fig. 1) where they depart but little from the generalized, biting type. In most other Hymenoptera the mandibles are used for what may be termed industrial purposes more than for feeding, and the ligula is modified into an organ for lapping or sucking nectar. In the higher types of bees this organ is elongated into a kind of tongue which, in some cases, exceeds in length that of the entire insect. In these instances the labial palpi and maxillae are also correspondingly lengthened and form with the ligula, a definite proboscis

(fig. 1). The thorax (fig. 2) is chiefly characterized by the fusion of its last segment with the *propodeum* or first segment of the abdomen. In the saw-flies this union is scarcely evident, but in all other Hymenoptera it is a pronounced feature and the second abdominal segment (or first apparent segment) is constricted to form a waist or *petiole*. The wings have departed very widely from the primitive type of venation and almost every transition can be found from the well developed condition seen in saw-flies to some of the parasitic forms where there is only a single vein to the fore-wings or even no veins at all. At the bases of the fore-wings are small scale-like plates or *tegulae*, which afford important characters used in classification. Most members of the order fly with the wings of a side interlocked by a row of hooklets. In the female the abdomen bears an elaborate ovipositor, typically composed of three pairs of valves. The first pair arises from the eighth segment and forms the lancets, while the other pairs arise from the ninth segment and form the lancet sheath and the so-called sting palps respectively (fig. 3). In addition to functioning as an egg-laying instrument the ovipositor is used in saw-flies for sawing niches in plants into which the eggs are lodged: in ichneumon flies and their allies it is often employed in stabbing their insect hosts preparatory to laying their eggs within the bodies of the latter: in bees, wasps and some ants it is used for stinging, a habit which is found in no other insects.

Classification.—Hymenoptera are grouped into two main sub-orders and these, along with their chief sub-divisions, are enumerated below.

SUB-ORDER I. SYMPHYTA

Abdomen with no definite basal constriction or waist: trochanters two-jointed. Larvae generally caterpillars with a variable number of legs.

Superfamily Tenthredinoidea (fig. 5). Included in this division are all the more primitive members of the order: they do not exhibit the specialized habits and instincts of the Apocrita and their larvae are almost entirely plant-feeders. The most important family is the *Tenthredinidae* or saw-flies (*q.v.*) which are distinguished by two large spines or spurs to each fore tibia. Their larvae are caterpillars which feed upon the leaves of plants, and those of a number of species are injurious to cultivated plants and forest trees. The ovipositor is usually elaborately toothed,

which the trochanters are single jointed. The *Parasitica* include the following super-families.

The Ichneumonoidea have the pronotum extending back to the tegulae, the antennae are not elbowed and the fore-wings have a dark mark or stigma (fig. 7). Without exception the larvae of all members of this group are parasites preying upon some stage in

FIG. 5.—LIFE HISTORY OF CHALCID (DIBRACHYS CAVUS)

The sub-order Apocrita is chiefly characterized by the narrowly constricted waist of the adult and by the legless condition of the larvae

the life-cycle of other insects and are consequently of great economic importance. (See ICHNEUMON FLV.)

The Cynipoidea include the gall-wasps or gall-flies which differ from the ichneumons in the absence of a stigma to the fore-wings and in the trochanters being usually single-jointed, unlike other *Parasitica*. In the family *Cynipidae* many of the species lay their eggs in various plant-tissues which react in such a way that galls are produced wherein their development is completed. These galls are of characteristic form for each species, the oak apple and bedeguar of the rose being familiar examples. Other members of the family are inquilines, living within the galls and bearing a close resemblance to the true makers of the latter. The *Figitidae* are mostly parasites of fly larvae and of aphids.

The Chalcidoidea or Chalcid-wasps are very small insects with elbowed antennae and with the pronotum not extending back to the tegulae. The group includes more than 16 families, most of the members of which are either parasites of the eggs, larvae or pupae of other insects or are hyperparasites. A small number are plant-feeders living in seeds, in figs, or form galls on cereals and grasses. The fig-insects are very numerous and certain of these are important agents in the pollination of the flowers, and have been introduced for economic purposes into lands where they were absent. The parasitic forms are of great practical value, in that they destroy vast numbers of injurious insects: certain of these exhibit the phenomenon of polyembryony, which is dealt with in the article INSECTS. Chalcids often exhibit beautiful metallic coloration, and can be recognized by the wing-veins being reduced to a single stem.

The Proctotrypoidea resemble the Aculeates in that the ovipositor issues from the apex of the abdomen, but the trochanters are 2-jointed. The first mentioned character, along with the fact that the pronotum reaches back to the tegulae, separates them from the Chalcids (fig. 5). They are all very small or minute insects with greatly reduced venation and many are wingless. They live as parasites or hyperparasites of other insects, frequently in the eggs which they destroy in large numbers. The largest of the eight chief families are the *Platygasteridae* which mainly para-

FIG. 4.—LIFE-HISTORY OF PEAR SAWFLY (ERIOCAMPOIDES LIMACINA)

The larvae are plant feeders, those feeding openly on leaves being caterpillars, often with six or more pairs of feet

and is used for sawing notches to enable the eggs to be laid in plant tissues. The *Cephidæ* or stem saw-flies are a small group, whose larvae feed in the stems of various plants, while those of the *Siricidae* or wood-wasps bore into the wood of trees.

SUB-ORDER II. APOCRITA

Abdomen with a basal constriction or waist: trochanters 1- or 2-jointed. Larvae embryonic or vermiform without legs.

The great group is divisible into the *Parasitica* which generally have 2-jointed trochanters and the *Aculeata* or stinging forms in

sitize gall midges, their larvae often living in the brain or stomach of their hosts. Like the Chalcids the Proctotrypids are beneficial.

The succeeding super-families form the series Aculeata or stinging Hymenoptera and in these the ovipositor issues from the apex of the abdomen, whereas in the Parasitica it issues some distance in front of the extremity.

The Formicoidea or ants form a very natural assemblage which

FROM SYLVESTRI, "PLATYGASTER DRYOMIAE" IN "BOLLETTINO DEL LABORATORIO DI ZOOLOGIA" (SCUOLA SUPERIORE D'AGRICOLTURA IN PORTICI)

FIG. 6.—A FEMALE PROCTOTRYPID (*PLATYGASTER DRYOMIAE*)
On the right the female is seen in the act of oviposition in an egg (O), of a gall midge, on a leaf

are easily recognized by the greatly constricted "waist" and by the petiole being marked by one or two nodes: the pronotum extends back to the tegulae in the winged forms and the antennae are elbowed. The females are differentiated into winged "queens" and wingless workers of varied forms; each species of ant leads a complex social life which presents many phases of surpassing interest. (See ANT and SOCIAL INSECTS.)

The Sphecoidea or digging wasps (fig. 8) are not very sharply marked off from the Vespoidea, except by the fact that the pronotum does not reach back to the tegulae. For the most part they are to be regarded as beneficial insects from the fact that they are predators seizing other insects, which they carry off to their cells as food for their larvae. All are solitary insects which construct cells for their brood either below ground or in dry wood or stems. There are 12 families, the largest being the *Sphesidae*.

The Vespoidea include a large number of other digging wasps together with the social wasps. The pronotum generally reaches back to the tegulae but there are exceptions. Among the solitary species the *Mutillidae* are parasites in bumble-bees' nests and their females are wingless. Many of the *Pompilidae* provision their cells with spiders: they are often large insects with slender bodies and elongate hind-legs. The *Scoliidae* are robust, hairy wasps which often provision their cells with chafer larvae and chiefly inhabit warm countries. The *Chrysididae* or ruby-tailed wasps are beautiful metallic green or blue or ruby insects, which lay their eggs in the nests of bees and wasps where their larvae either prey upon those of their hosts or devour their food. In this family only three or four abdominal segments are visible, the remainder forming a retractile tube containing the ovipositor. The true wasps have their wings folded lengthwise in repose and the fore-legs are of normal build—not specialized for digging as in the fossorial groups. The *Vespidae* or social wasps have "queens" and "workers" as in ants, but both forms are winged, while the *Eumenidae* or solitary true wasps have no such differentiation into castes. (For the habits of these two families see WASP and SOCIAL INSECTS.)

The Apoidea include the solitary and social bees which agree with the Sphecoidea in the pronotum not extending back to the tegulae but differ from them in having the hind tarsi dilated, while the hairs of the head and thorax are feathery or plumose. The glossa or tongue is well developed and often exceedingly long and the food consists of nectar and pollen. The larvae are fed upon a similar diet, except that the nectar is regurgitated as honey before being served to them. These substances are stored in the cells and the latter are never provisioned with animal food. Most bees are solitary in habit, but those of the families *Bombidae* and *Apidae* are social insects resembling ants and wasps in the occurrence of a worker caste. (See BEE and SOCIAL INSECTS.)

Reproduction and Development.—One of the most interesting facts with regard to reproduction in Hymenoptera, is the wide occurrence of parthenogenesis which obtains among members of all the great groups. The best known instance is in the honey-bee, in which the unfertilized eggs produce males (drones): in the gall-wasps or *Cynipidae* both sexes may be produced from unfertilized eggs and the generations which arise in this way alternate with those produced by the usual sexual method. In other of the gall wasps males are unknown: parthenogenesis is also very frequent in saw-flies and Chalcid wasps.

The larvae of the Symphyta are plant-feeders: those which feed openly on leaves are caterpillars, often with six or more pairs of abdominal feet (fig. 4), but in the stem- and wood-borers these appendages are absent and the thoracic limbs are reduced to mere tubercles. Among the Apocrita the larvae are usually hatched in immediate contact with an abundance of food: they are in consequence degenerate creatures devoid of limbs and of almost all traces of organs of special sense (fig. 5). In the parasitic groups hypermetamorphosis (see INSECTS) is very frequent, the larvae being hatched in forms very different from that assumed in the final instar. In a few cases the eggs are laid away from the hosts and the larvae upon hatching are active creatures of the type termed a planidium. The planidium seeks out its host and having found it, assumes the legless maggot-like form common to all Apocrita. Some of the parasitic species live externally on their hosts and feed by piercing the integument with their mouth-parts, but the largest number are endoparasites. In the latter case the female parent drives her ovipositor into the host and lays one or more eggs wherever the larvae will find abundant food. Many of the minute Chalcidoidea and Proctotrypoidea complete their development within the eggs of other insects: others parasitize the larvae or pupae or, more rarely, adult insects, and death of the host finally supervenes. The digging or fossorial wasps feed their brood with captured insects, which are stored away in cells along with a single egg: the wasp larva, upon hatching, thus finds its life's food-supply immediately at hand. The true wasps feed their brood with animal food including many insects, from time to time, very much as a bird does her fledglings, while bees entirely resort to honey and pollen. Thus, we find throughout the order a degree of care for the offspring, not attained in other insects, which has led to the development of social life in certain groups. When fully fed most Hymenoptera pupate in cocoons: silk is commonly used for their construction and among the ichneumon flies and their allies, these cocoons are often elaborate and beautiful objects.

Geographical Distribution.—Hymenoptera are found in all except the most inhospitable regions of the globe, but the order, as a whole, has not penetrated to such remote parts as have the Apterygota and Coleoptera. Bees, for example, are dependent upon the existence of flowering plants and are not found outside their range: some, such as the giant *Xylocopa* or carpenter bees are mainly tropical or sub-tropical, while bumble bees are essentially creatures of temperate climates and are generally confined to the mountains in the tropics; they are absent from almost the whole of Africa, the plains of India and none are indigenous to Australia or New Zealand. The honey-bee (*Apis mellifica*) has been introduced into most countries of the world, and some of the injurious saw-flies enjoy a very wide distribution, mainly through the agency of commerce. Among the Chalcid wasps the family *Aganidae* or fig-insects occurs wherever trees of the fig kind flourish, but are not found outside that limit: certain other Chalcids (*Eucharidae*) are mainly tropical and are confined to where their particular ant hosts flourish. Perhaps the most interesting fact concerning the distribution of Hymenoptera is the great paucity of forms found in New Zealand, where they are represented by little more than 300 species, as compared with over 6,000 found in Australia.

Geological Distribution.—Forms ancestral to Hymenoptera are represented by the extinct order Protohymenoptera, whose remains occur in the Lower Permian of Kansas. The first true members of the order to appear in geological history are wood wasps of the genus *Pseudosirex* from the Upper Jurassic of Bavaria. In Tertiary times the order is represented by ants, bees and other forms which differ relatively little from those found living to-day.

Natural History.—Hymenoptera are mostly of small or moderate size: only a few members of the order are very large insects, the giants being certain of the saw-flies and digging wasps of the family *Pompilidae*, some of the latter attaining a length of three inches. On the other hand, many of the parasitic forms are among the smallest of all insects, notably those which live as egg-parasites; certain Chalcid wasps of family *Mymaridae* or "fairy flies" measure only .21mm. in length.

Hymenoptera are essentially terrestrial and aerial in habit. The only exceptions are those which parasitize the larvae or eggs of aquatic insects: the "fairy fly" *Polynema natans* swims readily beneath the water by means of its wings and seeks out the eggs of the water boatmen (*Notonecta*) as the host for its larvae. In a number of species the parasitic groups greatly exceed the remainder of the order. No order of terrestrial insects escapes their attacks, and even larvae deep in the soil or boring in the solid wood of trees are by no means immune. As a rule the length of the ovipositor is greatest in those parasites such as *Thalessa* and *Rhyssa* which have to force this organ through a depth of wood, in order to reach their hosts (fig. 7). One of the most remarkable cases of parasitism is found in a proctotrypid, *Riela manticida* which, according to L. Chopard, passes its development in the eggs of the praying mantis. The adult parasites, upon emergence, make their way to a mantis, upon whose body they settle down: in this situation they cast off their wings and live ectoparasitically. If the mantis be a female which has commenced egg-laying, the *Riela* migrates to the extremity of the body, in order to lay its eggs in the viscid mass of the mantis' egg-capsule as it is being formed. Parasites which settle upon male mantids are probably short-lived and perish. The digging wasps store their cells with other insects or spiders and as a rule they sting their prey first and reduce it to a condition of immobility without actually killing it: in other cases the prey is killed, but since it retains its fresh condition up to several weeks, it is presumed that the injected venom exercises an antiseptic influence. Fabre's observations upon the *Sphex*

(*Ammophila*), which stings its caterpillar prey in successive segments of its body, have often been quoted. The French observer maintained that this insect (fig. 8) had a sort of intuitive knowledge of the inner anatomy of its victim, the stings being administered in the ganglionic nerve centres, thereby inducing paralysis, a conclusion which is scarcely warranted by the facts at his disposal. The number of times a prey is stung appears to vary from once up to about a dozen: in addition to being stung the victim is vigorously pinched by the jaws of the *Sphex* particularly when it has only been stung a few times and subsequent paralysis occurs in each case. The nature of the prey of digging wasps is often very constant for particular species. Thus *Philanthus triangulum* stores its nest with honey-bees, while species of *Bembex* prey upon large Diptera and the powerful *Pep-sis femoratus* stores its burrows with the great Tarantula spiders.

Among bees, wasps and some ants, the capacity for stinging is employed for defensive purposes and the usual glands which are found at the base of the ovipositor are especially large in these insects. Their secretions have irritating properties to which the sting is due, those of ants containing formic acid.

FROM RILEY AND HOWARD, "INSECT LIFE" U.S. DEPT. OF AGRICULTURE

FIG. 7.—ICHNEUMON FLY (*RHYSSA PERSUASORIA*) OVIPOSITING

FROM IMMS, "TEXT-BOOK OF ENTOMOLOGY" (METHUEN & CO.)

FIG. 8.—FEMALE SPHEG (*AMMOPHILA SABULOSA*) (TWICE ACTUAL SIZE)

The genus *sphex* includes digging wasps, which store their cells with caterpillars and other insects. The prey is paralyzed by stinging and remains fresh during the time the *sphex* devours it

The nest-building habit is another feature of Hymenoptera. Digging wasps make simple burrows in the ground, and many burrowing bees make branched tunnels. Other bees excavate wood or make their brood-chambers in hollow stems, while the true wasps work up dry fragments of wood with their saliva to form a sort of paper with which they construct the cells of their nest. The social bees secrete wax from their own bodies with which they build up the combs of their nest. There are numerous Hymenoptera that areinquilines—insects which construct no nests of their own and utilize, instead, those of other species: in some cases their larvae consume the food provided by the rightful owners for their own brood, and in others, they devour the larvae of the host thus becoming true parasites.

The most interesting of all features associated with Hymenoptera is their social life, which forms the subject of a separate article. (See SOCIAL INSECTS.)

Economic Importance.—The chief injurious members of the order belong to the Symphyta and the larvae of a number of saw-flies are exceedingly destructive. Thus, the turnip saw-fly *Athalia spinarum* destroys the foliage of the turnip crop in Britain and many parts of Europe: the pear slug saw-fly (*Eriocampoides limacina*) skeletonizes the leaves of pears in Europe, North America, Australia and New Zealand and *Lygaeonematus erichsonii* is destructive to larch on both sides of the Atlantic. The gooseberry saw-fly (*Nematus ribesii*) is a well known pest of gooseberries in gardens in many parts of Europe, as well as in North America, and the larvae of various species of *Lophyrus* are destructive to pines. Wood-wasps (*Siricidae*) bore into timber in many parts of the world and the stem-borers (*Cephidæ*), are especially injurious to cereals. The Apocrita are almost wholly beneficial insects, the honey-bee yields bees-wax and honey, while the important rôle played by the parasitic forms in destroying injurious insects, has already been dilated upon. The recent introduction of the Chalcid-wasp *Aphelinus mali* into New Zealand is an example of the practical utilization of parasitic Hymenoptera, and the species in question has now largely controlled the woolly aphids of the apple in that territory. Among other Chalcids certain fig-insects (*Blastophaga*) are employed in the pollination of the flowers of the fig, and have been previously mentioned. On the other hand, a small number of Chalcids are injurious, notably those whose larvae live in seeds such as species of *Megastigmus* which attack those of conifers, while larvae of *Harmolita* form stem galls on cereals and grasses.

BIBLIOGRAPHY.—In an order so extensive and diverse as Hymenoptera the reader will find very few comprehensive works, the literature mainly dealing with individual groups. The European species are monographed by E. and E. André, *Species des Hyménoptères d'Europe et d'Algérie* (1879-1913) and the world's species are catalogued by C. G. de Dalla Torre, *Catalogus Hymenopterorum* (Leipzig, 1892-1902). A useful guide to the North American forms is provided by H. L. Viereck and collaborators in *The Hymenoptera or Wasp-like Insects of Connecticut* (Bull. 22 State Geol. and Nat. Hist. Survey: Hartford, Conn., 1916) and for their classification consult W. H. Ashmead, *Proc. U.S. Nat. Mus.* xxiii, 1901. For the saw-flies and gall-flies the accounts given in C. Schröder's *Insekten Mitteleuropas*, vol. iii. (Stuttgart, 1914) are concise and well illustrated, while the British species are described by P. Cameron, *British Phytophagous Hymenoptera* (London, Roy. Soc., 1882-92), which is provided with accurate coloured plates. A useful popular account of the galls produced by Cynipidae is E. T. Connold, *British Plant Galls* (1909). For the North American galls see M. T. Cook, *Galls and Insects Producing them* (Ohio Nat., vols. ii-iv, 1902-04), and A. Cosens, *A Contribution to the Morphology and Biology of Insect Galls* (Trans. Canad. Inst. vol. ix., 1912). For parasitism and the forms exhibiting this habit the following works are important: W. H. Ashmead, *Classification of the Chalcid Flies* (Mem. Carnegie Mus. 1, 1904) and the same author's *Monograph of the North American Proctotrypidæ* (Bull. 45, U.S. Nat. Mus. 1893); L. O. Howard, *The Biology of the Hymenopterous Insects of the family Chalcididae* (Proc. U.S. Nat. Mus., xiv., 1891); L. O. Howard and W. F. Fiske, *The Importation into the United States of the Parasites of the Gypsy Moth*, etc. (U.S. Dept. Agric., Entom. Bull. 91: 1911); other references are given in the article ICHNEUMON-FLY (q.v.).

The Aculeata have a very extensive literature and among the more important works are: E. Saunders, *Hymenoptera Aculeata of the British Islands* (1896); H. St. J. Donisthorpe, *British Ants* (1927); W. M. Wheeler, *Ants* (1910); P. and N. Rau, *Wasp Studies Afield* (Princeton, 1918); G. W. and E. G. Peckham, *Wasps, Social and*

Solitary (1905); for other references see SOCIAL INSECTS.

In addition to the foregoing numerous observations on the habits and behaviour of Hymenoptera are given in J. H. Fabre, *Souvenirs Entomologiques* (1879-1905), many of which are translated into English.

HYMETTUS, a mountain in Attica, bounding the Athenian plain on the south-east (3,370 ft.), has always been famous for its honey. The spring mentioned by Ovid (*Ars Amat.* iii. 687) is probably near the monastery of Syriani or Kaesariani on the western slope and identical with that known as Κύλλον Πήρα said to be a remedy for childlessness. The marble of Hymettus, which often has a bluish tinge, was used for building in ancient Athens, and even for sculpture; although the white marble of Pentelicon was preferred for both purposes.

See E. Dodwell, *Classical and Topographical Tour* (1819), i. 483.

HYMNS. The word "hymn" (ὕμνος) was employed by the ancient Greeks to signify a song or poem composed in honour of gods, heroes or famous men, or to be recited on some joyful, mournful or solemn occasion. But hymns are actually much older than any Greece can show; the ancient Chinese "hymned" the Ruler of Heaven; Assyria, Egypt and India have all left us records of early hymns. The Athenian dramatists (Euripides most frequently) use the word and its cognate verbs of odes in praise of conquerors at the public games; they also describe by them metrical oracles and apophthegms, martial, festal and hymeneal songs, dirges and lamentations or incantations of woe.

Hellenic hymns, according to this conception of them, have come down to us, some from a very early and others from a late period of Greek classical literature.

The Romans did not adopt the word "hymn"; nor have we many Latin poems of the classical age to which it can properly be applied. There are, however, a few—such as the simple and graceful "Dianae sumus in fide" ("Dian's votaries are we") of Catullus, and "Dianam tenerae dicite virgines" ("Sing to Dian, gentle maidens") of Horace—which approach much more nearly than anything Hellenic to the form and character of modern hymnody.

Hebrew Hymnody.—For the origin and idea of Christian hymnody we must look, not to Gentile, but to Hebrew sources. St. Augustine's definition of a hymn, generally accepted by Christian antiquity, may be summed up in the words, "praise to God with song" ("cum cantico"); Bede understood the "canticum" as properly requiring metre; though he thought that what in its original language was a true hymn might retain that character in an unmetrical translation. Modern use has enlarged the definition; Roman Catholic writers extend it to the praises of saints; and the word now comprehends rhythmical prose as well as verse, and prayer and spiritual meditation as well as praise.

The modern distinction between psalms and hymns is arbitrary (see PSALMS).

In the New Testament we find our Lord and His apostles singing a hymn (ὕμνησαντες ἐξῆλθον), after the institution of the Lord's Supper; St. Paul and Silas doing the same (ὕμνον τὸν θεόν) in their prison at Philippi; St. James recommending psalm-singing (ψαλλέτω) and St. Paul "psalms and hymns and spiritual songs (ψαλμοῖς καὶ ὕμνοις καὶ ᾠδαῖς πνευματικαῖς) St. Paul also, in the 14th chapter of the first epistle to the Corinthians, speaks of singing (ψαλλῶ) and of every man's psalm (ἐκαστος ὕμνον ψαλμὸν ἔχει), in a context which plainly has reference to the assemblies of the Corinthian Christians for common worship. All the words thus used were applied by the LXX. to the Davidical psalms; it is therefore possible that these only may be intended, in the different places to which we have referred. But there are in St. Paul's epistles several passages (Eph. v. 14; 1 Tim. iii. 16; 1 Tim. vi. 15, 16; 2 Tim. ii. 11, 12) which have so much of the form and character of later Oriental hymnody as to have been supposed by Michaelis and others to be extracts from original hymns of the Apostolic age.

Eastern Church Hymnody.—The hymn of our Lord, the precepts of the apostles, the angelic song at the nativity, and "Benedicite omnia opera" are referred to in a curious metrical prologue to the hymnary of the Mozarabic Breviary as precedents for the practice of the Western Church. Philo describes the

Therapeutae (*q.v.*) of the neighbourhood of Alexandria as composers of original hymns which were sung at their great religious festivals.

The practice, not only of singing hymns, but of singing them antiphonally, appears, from the well-known letter of Pliny to Trajan, to have been established in the Bithynian churches at the beginning of the 2nd century. This agrees well, in point of time, with the tradition recorded by the historian Socrates, that Ignatius (who suffered martyrdom about A.D. 107) was led by a vision or dream of angels singing hymns in that manner to the Holy Trinity to introduce antiphonal singing into the church of Antioch, from which it quickly spread to other churches.

The Greek hymnody contemporary with Ephraem followed, with some licence, classical models. One of its favourite metres was the Anacreontic; but it also made use of the short anapaestic, Ionic, iambic and other lyrical measures, as well as the hexameter and pentameter. Its principal authors were Methodius, bishop of Olympus, who died about A.D. 311, Synesius, who became bishop of Ptolemais in Cyrenaica in 410, and Gregory Nazianzen, for a short time (380-381) patriarch of Constantinople. They have found an able English translator in the Rev. Allen Chatfield (*Songs and Hymns of Earliest Greek Christian Poets*, 1876). Among the most striking of their works are μνήμεο Χριστέ ("Lord Jesus, think of me"), by Synesius; σέ τὸν ἄφθιτον μονάρχην ("O Thou, the One Supreme") and τί σοι θέλεις γενέσθαι ("O soul of mine, repining"), by Gregory; also ἀνῶθεν παρθένου ("The Bridegroom cometh"), by Methodius. There continued to be Greek metrical hymn-writers, in a similar style, till a much later date. Sophronius, patriarch of Jerusalem in the 7th century, wrote seven Anacreontic hymns; and St. John Damascene, one of the most copious of the second school of "Melodists," was also the author of some long compositions in iambic trimeters.

Period of Arian Controversy.—An important development of hymnody at Constantinople arose out of the Arian controversy. Early in the 4th century Athanasius had rebuked, not only the doctrine of Arius, but the light character of certain hymns by which he endeavoured to make that doctrine popular. When, towards the close of that century (398), St. John Chrysostom was raised to the metropolitan see, the Arians, who were still numerous at Constantinople, had no places of worship within the walls; but they were in the habit of coming into the city at sunset on Saturdays, Sundays and the greater festivals, and congregating in the porticoes and other places of public resort, where they sang, all night through, antiphonal songs, with "acroteleutia" (closing strains, or refrains), expressive of Arian doctrine, often accompanied by taunts and insults to the orthodox. Chrysostom was apprehensive that this music might draw some of the simpler church people to the Arian side; he therefore organized, in opposition to it, under the patronage and at the cost of Eudoxia, the empress of Arcadius (then his friend), a system of nightly processional hymn-singing, with silver crosses, wax-lights and other circumstances of ceremonial pomp. Riots followed, with bloodshed on both sides. This led to the suppression, by an imperial edict, of all public Arian singing.

Melodists.—The controversies and persecutions of the 8th and succeeding centuries turned the thoughts of the "melodists" of the great monasteries of the Studium at Constantinople and St. Saba in Palestine and their followers, and those of the adherents of the Greek rite in Sicily and South Italy (who suffered much from the Saracens and the Normans), into a less picturesque but more strictly theological course; and the influence of those controversies, in which the final success of the cause of "Icons" was largely due to the hymns, as well as to the courage and sufferings, of these confessors, was probably the cause of their supplanting, as they did, the works of the older school.

Among the "melodists" of this latter Greek school there were many saints of the Greek church, several patriarchs and two emperors—Leo the Philosopher, and Constantine Porphyrogenitus, his son. Their greatest poets were Theodore and Joseph of the Studium, and Cosmas and John (called Damascene) of St. Saba. Neale translated into English verse several selected portions, or centoës, from the works of these and others, together with four

selections from earlier works by Anatolius. Some of his translations—particularly “The day is past and over,” from Anatolius, and “Christian, dost thou see them,” from Andrew of Crete—have been adopted into hymn-books used in many English churches; and the hymn “Art thou weary,” which is rather founded upon than translated from one by Stephen the Sabaite, has obtained still more general popularity.

Western Church Hymnody.—It was not till the 4th century that Greek Hymnody was imitated in the West, where its introduction was due to two great lights of the Latin Church—St. Hilary of Poitiers and St. Ambrose of Milan.

Hilary was banished from his see of Poitiers in 356, and was absent from it for about four years, which he spent in Asia Minor, taking part during that time in one of the councils of the Eastern Church. He thus had full opportunity of becoming acquainted with the Greek church music of that day; and he wrote (as St. Jerome, who was thirty years old when Hilary died, and who was well acquainted with his acts and writings, and spent some time in or near his diocese, informs us) a “book of hymns,” to one of which Jerome particularly refers, in the preface to the second book of his own commentary on the epistle to the Galatians. Isidore, archbishop of Seville, who presided over the fourth council of Toledo, in his book on the offices of the church, speaks of Hilary as the first Latin hymn-writer; that council itself, in its 13th canon, and the prologue to the Mozarabic hymnary (which is little more than a versification of the canon), associate his name, in this respect, with that of Ambrose.

Of the part taken by Ambrose, not long after Hilary's death, in bringing the use of hymns into the church of Milan, we have a contemporary account from his convert, St. Augustine. Justina, mother of the emperor Valentinian, favoured the Arians, and desired to remove Ambrose from his see. The “devout people,” of whom Augustine's mother, Monica, was one, combined to protect him, and kept guard in the church. “Then,” says Augustine, “it was first appointed that, after the manner of the Eastern churches, hymns and psalms should be sung, lest the people should grow weary and faint through sorrow; which custom has ever since been retained, and has been followed by almost all congregations in other parts of the world.” He describes himself as moved to tears by the sweetness of these “hymns and canticles.”

It is not, however, to be assumed that the hymnody thus introduced by Ambrose was from the first used according to the precise order and method of the later Western ritual. To bring it into (substantially) that order and method appears to have been the work of St. Benedict. Walafrid Strabo, the earliest ecclesiastical writer on this subject (who lived at the beginning of the 9th century), says that Benedict, on the constitution of the religious order known by his name (about 530), appointed the Ambrosian hymns to be regularly sung in his offices for the canonical hours. Hence, probably originated the practice of the Italian churches, and of others which followed their example, to sing certain hymns (Ambrosian, or by the early successors of the Ambrosian school) daily throughout the week, at “Vespers,” “Lauds” and “Nocturns,” and on some days at “Compline” also—varying them with the different ecclesiastical seasons and festivals, commemorations of saints and martyrs and other special offices. The national rituals were probably the “Ambrosian” and the “Mozarabic” (of Spain).

The hymns of which the use was thus established and authorized were those which entered into the daily and other offices of the church, afterwards collected in the “Breviaries”; in which the hymns “proper” for “the week,” and for “the season,” continued for many centuries, with very few exceptions, to be derived from the earliest epoch of Latin Church poetry—reckoning that epoch as extending from Hilary and Ambrose to the end of the pontificate of Gregory the Great. The “Ambrosian” music, to which those hymns were generally sung down to the time of Gregory, was more popular and congregational than the “Gregorian,” which then came into use, and afterwards prevailed.

In the 5th and early in the 6th century the priest Sedulius, whose reputation perhaps exceeded his merit; Elpis, a noble Roman lady (considered, by an erroneous tradition, to have been

the wife of the philosophic statesman Boetius); Pope Gelasius I.; and Ennodius, bishop of Pavia, were hymn-writers. Sedulius and Elpis wrote very little from which hymns could be extracted; but the small number taken from their compositions obtained wide popularity, and have since held their ground. Gelasius was of no great account as a hymn-writer; and the works of Ennodius appear to have been known only in Italy and Spain. The latter part of the 6th century produced Pope Gregory the Great and Venantius Fortunatus, an Italian poet, the friend of Gregory, and the favourite of Radegunda, queen of the Franks, who died (609) bishop of Poitiers. Eleven hymns of Gregory, and twelve or thirteen (mostly taken from longer poems) by Fortunatus, came into general use in the Italian, Gallican and British churches. Eleven metrical hymns are attributed to Bede and there are also in one of Bede's works (*Collectanea et flores*) two rhythmical hymns of considerable length on the Day of Judgment, with the refrains “In tremendo die” and “Attende homo,” both irregularly rhymed, and, in parts, not unworthy of comparison with the “Dies Irae.” Paulinus, patriarch of Aquileia, contemporary with Paul, wrote rhythmical trimeter iambics in a manner peculiar to himself. Theodulph, bishop of Orleans (793–835), author of the famous processional hymn for Palm Sunday in hexameters and pentameters, “Gloria, laus, et honor tibi sit, Rex Christe Redemptor” (“Glory and honour and praise be to Thee, King Christ the Redeemer”), and Hrabanus Maurus, archbishop of Mainz, the pupil of Alcuin, and the most learned theologian of his day, enriched the church with some excellent works.

Sequences.—The invention of “sequences” by Notker (d. 912), may be regarded as the beginning of the later mediæval epoch of Latin hymnody. In the eucharistic service, in which (as has been stated) hymns were not generally used, it had been the practice, except at certain seasons, to sing “laud,” or “Alleluia,” between the epistle and the gospel, and to fill up what would otherwise have been a long pause, by extending the cadence upon the two final vowels of the “Alleluia” into a protracted strain of music. It occurred to Notker that, while preserving the spirit of that part of the service, the monotony of the interval might be relieved by introducing at that point a chant of praise specially composed for the purpose. With that view he produced the peculiar species of rhythmical composition which obtained the name of “sequentia” (probably from following after the close of the “Alleluia”), and also that of “prosa,” because its structure was originally irregular and unmetrical, resembling in this respect the Greek “troparia,” and the “Te Deum,” “Benedicite” and canticles. That it was in some measure suggested by the forms of the later Greek hymnody seems probable, both from the intercourse (at that time frequent) between the Eastern and Western churches, and from the application by Ekkehard, in his biography and elsewhere (e.g., in Lyndwood's *Provinciale*), of some technical terms, borrowed from the Greek terminology, to works of Notker and his school and to books containing them.

The “Golden Sequence,” “Veni, sancte Spiritus” (“Holy Spirit, Lord of Light”), is an early example of the transition of sequences from a simply rhythmical to a metrical form. Archbishop Trench, who esteemed it “the loveliest of all the hymns in the whole circle of Latin sacred poetry,” inclined to give credit to a tradition which ascribes its authorship to Robert II., king of France, son of Hugh Capet. Others have assigned to it a later date—some attributing it to Pope Innocent III., and some to Stephen Langton, archbishop of Canterbury.

Dies Irae and Stabat Mater.—But the two most widely celebrated of all this class of compositions—works which have exercised the talents of the greatest musical composers, and of innumerable translators in almost all languages—are the *Dies Irae* (“That day of wrath, that dreadful day”), by Thomas of Celano, the companion and biographer of St. Francis of Assisi, and the *Stabat Mater dolorosa* (“By the cross sad vigil keeping”) of Jacopone, or Jacobus de Benedictus, a Franciscan humorist and reformer, who was persecuted by Pope Boniface VIII. for his satires on the prelacy of the time, and died in 1306. Besides these, the 13th century produced the famous sequence *Lauda Sion salvatorem* (“Sion lift thy voice and sing”), and the four other

well-known sacramental hymns of St. Thomas Aquinas, viz. *Pange lingua gloriosi corporis mysterium* ("Sing, my tongue, the Saviour's glory"), *Verbum supernum prodiens* ("The Word, descending from above"—not to be confounded with the Ambrosian hymn from which it borrowed the first line), *Sacris solemnis juncta sint gaudia* ("Let us with hearts renewed our grateful homage pay"), and *Adoro Te devote, latens Deitas* ("O Godhead hid, devoutly I adore Thee")—a group of remarkable compositions, written by him for the then new festival of Corpus Christi, of which he induced Pope Urban IV. (1261-1265) to decree the observance.

Before the time of the Reformation, the multiplication of sequences (often as unedifying in matter as unpoetical in style) had done much to degrade the common conception of hymnody. In some parts of France, Portugal, Sardinia and Bohemia, their use in the vernacular language had been allowed. In Germany also there were vernacular sequences as early as the 12th century, specimens of which may be seen in the third chapter of C. Winkworth's *Christian Singers of Germany*. Scoffing parodies upon sequences are said to have been among the means used in Scotland to discredit the old church services. After the 15th century they were discouraged at Rome. They retained for a time some of their old popularity among German Protestants, and were only gradually relinquished in France. A new "prose," in honour of St. Maxentia, is among the compositions of Jean Baptiste Santeul; and Dr. Daniel's second volume closes with one written in 1855 upon the dogma of the Immaculate Conception.

German Hymnody.—Luther was a proficient in and a lover of music. He desired (as he says in the preface to his hymn-book of 1545) that this "beautiful ornament" might "in a right manner serve the great Creator and His Christian people." The persecuted Bohemian or Hussite Church, then settled on the borders of Moravia under the name of "United Brethren," had sent to him, on a mission in 1522, Michael Weiss, who not long afterwards published a number of German translations from old Bohemian hymns (known as those of the "Bohemian Brethren"), with some of his own. These Luther highly approved and recommended. He himself, in 1522, published a small volume of eight hymns, which was enlarged to 63 in 1527, and to 125 in 1545. He had formed what he called a "house choir" of musical friends, to select such old and popular tunes (whether secular or ecclesiastical) as might be found suitable, and to compose new melodies, for church use. His fellow labourers in this field (besides Weiss) were Justus Jonas, his own especial colleague; Paul Eber, the disciple and friend of Melancthon; John Walther, choir-master successively to several German princes, and professor of arts, etc., at Wittenberg; Nicholas Decius, who from a monk became a Protestant teacher in Brunswick, and translated the *Gloria in Excelsis*, etc.; and Paul Speratus, chaplain to Duke Albert of Prussia in 1525. Some of their works are still popular in Germany. Weiss's "Funeral Hymn," *Nun lasst uns den Leib begraben* ("Now lay we calmly in the grave"); Eber's *Herr Jesu Christ, wahr Mensch und Gott* ("Lord Jesus Christ, true Man and God"), and *Wenn wir in höchsten Nöthen sein* ("When in the hour of utmost need"); Walther's "New Heavens and new Earth" ("Now fain my joyous heart would sing"); Decius's "To God on high be thanks and praise"; and Speratus's "Salvation now has come for all," are among those which at the time produced the greatest effect, and are still best remembered.

Followers of Luther.—The principal hymn-writers of the Lutheran school, in the latter part of the 16th century, were Nikolaus Selnecker, Herman and Hans Sachs, the shoemaker of Nuremberg, also known in other branches of literature. They were succeeded by men of another sort, to whom F. A. Cunz gives the name of "master-singers," as having raised both the poetical and the musical standard of German hymnody:—Bartholomäus Ringwaldt, Ludwig Helmbold, Johannes Pappus, Martin Schalling, Rutilius and Sigismund Weingartner. The well-known English hymn, "Great God, what do I see and hear," is founded upon one by Ringwaldt. Of a quite different character were two of great beauty and universal popularity, composed by Philip Nicolai, a Westphalian pastor, during a pestilence in 1597, and published by

him, with fine chorales, two years afterwards. One of these (the "Sleepers wake! a voice is calling," of Mendelssohn's oratorio, *St. Paul*) belongs to the family of Advent or New Jerusalem hymns. The other, a "Song of the believing soul concerning the Heavenly Bridegroom" (*Wie schön leucht' uns der Morgenstern*—"O morning Star, how fair and bright"), became the favourite marriage hymn of Germany.

The hymns produced during the Thirty Years' War are characteristic of that unhappy time. In point of refinement and graces of style, the hymn-writers of this period excelled their predecessors. Their taste was chiefly formed by the influence of Martin Opitz, the founder of what has been called the "first Silesian school" of German poetry, who died comparatively young in 1639, and who, though not of any great original genius, exercised much power as a critic. Some of the best of these works were by men who wrote little. In the famous battle-song of Gustavus Adolphus, published (1631) after the victory of Breitenfeld, for the use of his army, *Verzage nicht du Häuflein klein* ("Fear not, O little flock, the foe"), we have almost certainly a composition of the hero-king himself, the versification corrected by his chaplain Jakob Fabricius (1593-1654) and the music composed by Michael Altenburg, whose name has been given to the hymn. This, with Luther's paraphrase of the 67th Psalm, was sung by Gustavus and his soldiers before the battle of Lützen in 1632. Two very fine hymns, one of prayer for deliverance and peace, the other of trust in God under calamities, were written about the same time by Matthäus Löwenstern, a saddler's son, poet, musician and statesman, who was ennobled after the peace by the emperor Ferdinand III. Martin Rinckhart, in 1636, wrote the "Chorus of God's faithful children" (*Nun danket alle Gott*—"Now thank we all our God"), introduced by Mendelssohn in his *Lobgesang*, which has been called the *Te Deum* of Germany, being usually sung on occasions of public thanksgiving. Weissel, in 1635, composed a beautiful Advent hymn ("Lift up your heads, ye mighty gates"), and J. M. Meyfart, professor of theology at Erfurt, in 1642, a fine adaptation of the ancient *Urbs beata Hierusalem*.

The most copious, and in their day most esteemed, hymn-writers of the first half of the 17th century, were Johann Heermann and Johann Rist. Heermann, a pastor in Silesia, the theatre (in a peculiar degree) of war and persecution, experienced in his own person a very large share of the miseries of the time, and several times narrowly escaped a violent death. His *Devoti musica cordis*, published in 1630, reflects the feelings natural under such circumstances. Next to Heermann and Rist in fertility of production, and above them in poetical genius, was Simon Dach, professor of poetry at Königsberg, who died in 1659.

Gerhardt.—The fame of all these writers was eclipsed in the latter part of the same century by three of the greatest hymnographers whom Germany has produced—Paul Gerhardt (1604-1676), Johann Franck (1618-1677) and Johann Scheffler (1624-1677), the founder of the "second Silesian school," who assumed the name of "Angelus Silesius." Gerhardt is by universal consent the prince of Lutheran poets. One of his hymns is well known and highly appreciated in English through Wesley's translation, "Commit thou all thy ways"; and the evening and spring-tide hymns ("Now all the woods are sleeping" and "Go forth, my heart, and seek delight") show an exquisite feeling for nature; while nothing can be more tender and pathetic than *Du bist zwar mein und bleibest mein* ("Thou'rt mine, yes, still thou art mine own"), on the death of his son. Franck, who was burgomaster of Guben in Lusatia, has been considered by some second only to Gerhardt. It was after his conversion to Roman Catholicism that Scheffler adopted the name of "Angelus Silesius," and published in 1657 his hymns, under a fantastic title, and with a still more fantastic preface.

The Pietists.—Towards the end of the 17th century, a new religious school arose, to which the name of "Pietists" was given, and of which Philipp Jakob Spener was esteemed the founder. He and his pupils and successors, August Hermann Francke and Anastasius Freylinghausen, all wrote hymns. Spener's hymns are not remarkable, and Francke's are not numerous.

Joachim Neander, a schoolmaster at Düsseldorf, and a friend

of Spener and Schütz (who died before the full development of the "Pietistic" school), was the first man of eminence in the "Reformed" or Calvinistic Church who imitated Lutheran hymnody. The Summer Hymn ("O Thou true God alone") and that on the glory of God in creation ("Lo, heaven and earth and sea and air") are instances of his best style.

With the "Pietists" may be classed Benjamin Schmolke and Dessler, representatives of the "Orthodox" division of Spener's school; Philipp Friedrich Hiller, their leading poet in South Germany; Gottfried Arnold and Gerhard Tersteegen, who were practically independent of ecclesiastical organization, though connected, one with the "Orthodox" and the other with the "Reformed" churches; and Nikolaus Ludwig, Graf von Zinzendorf. Schmolke, a pastor in Silesia, called the Silesian Rist (1672-1737), was perhaps the most voluminous of all German hymn-writers. He wrote 1,188 religious poems and hymns, a large proportion of which do not rise above mediocrity.

Gellert and Klopstock.—The transition from Tersteegen and Zinzendorf to Gellert and Klopstock marks strongly the reaction against Pietism which took place towards the middle of the 18th century. The *Geistlichen Oden und Lieder* of Christian F. Gellert were published in 1757, and are said to have been received with an enthusiasm almost like that which "greeted Luther's hymns on their first appearance." It is a proof of the moderation both of the author and of his times that they were largely used, not only by Protestant congregations, but in those German Roman Catholic churches in which vernacular services had been established through the influence of the emperor Joseph II. They became the model which was followed by most succeeding hymn-writers, and exceeded all others in popularity till the close of the century, when a new wave of thought was generated by the movement which produced the French Revolution. Klopstock, the author of the *Messiah*, cannot be considered great as a hymn-writer, though his "Sabbath Hymn" (of which there is a version in *Hymns from the Land of Luther*) is simple and good. Generally his hymns (ten of which are translated in Sheppard's *Foreign Sacred Lyre*) are artificial and much too elaborate.

The "Romantic" School.—Of the "romantic" school, which came in with the French Revolution, the two leading writers are Friedrich Leopold von Hardenberg, called "Novalis," and Friedrich de la Motte Fouqué, the celebrated author of *Undine* and *Sintram*—both romance-writers, as well as poets. The genius of Novalis was early lost to the world; he died in 1801, not thirty years old. Some of his hymns are very beautiful; but even in such works as "Though all to Thee were faithless," and "If only He is mine," there is a feeling of insulation and of despondency as to good in the actual world, which was perhaps inseparable from his ecclesiastical idealism. Fouqué survived till 1843.

The later German hymn-writers of the 19th century belong, generally, to the revived "Pietistic" school. Some of the best, Johann Baptist von Albertini, Friedrich Adolf Krummacher, and especially Karl Johann Philipp Spitta (1801-59) have produced works not unworthy of the fame of their nation.

British Hymnody.—After the Reformation, the development of hymnody was retarded, in both parts of Great Britain, by the example and influence of Geneva. Archbishop Cranmer appears at one time to have been disposed to follow Luther's course, and to present to the people, in an English dress, some at least of the hymns of the ancient church. In a letter to King Henry VIII. (Oct. 7, 1544), among some new "processions" which he had himself translated into English, he mentions the Easter hymn, *Salve, festa dies, toto memorabilis aevo* ("Hail, glad day, to be joyfully kept through all generations"), of Fortunatus. In the "Primer" of 1535 (by Marshall) and the one of 1539 (by Bishop Hilsey of Rochester, published by order of the vicar-general Cromwell) there had been several rude English hymns, none of them taken from ancient sources. King Henry's "Primer" of 1545 (commanded by his injunction of May 6, 1545 to be used throughout his dominions) was formed on the model of the daily offices of the Breviary; and it contains English metrical translations from some of the best-known Ambrosian and other early hymns. But in the succeeding reign different views prevailed.

A new direction had been given to the taste of the "Reformed" congregations in France and Switzerland by the French metrical translation of the Old Testament Psalms, which appeared about 1540. This was the joint work of Clément Marot, valet or groom of the chamber to Francis I., and Theodore Beza, then a mere youth, fresh from his studies at Orleans.

The translation commonly known as the "Old Version" of the Psalms, was begun by Thomas Sternhold, whose position in the household of Henry VIII., and afterwards of Edward VI., was similar to that of Marot with Francis I., and whose services to the former of those kings were rewarded by a substantial legacy under his will. Sternhold published versions of nineteen Psalms, with a dedication to King Edward, and died soon afterwards. A second edition appeared in 1551, with eighteen more Psalms added, of Sternhold's translating and seven others by John Hopkins, a Suffolk clergyman. The work was continued during Queen Mary's reign by British refugees at Geneva, the chief of whom were William Whittingham, afterwards dean of Durham, who succeeded John Knox as minister of the English congregation there, and William Kethe or Keith, said by Strype to have been a Scotsman. They published at Geneva in 1556 a service-book, containing fifty-one English metrical psalms, which number was increased, in later editions, to eighty-seven. On the accession of Queen Elizabeth, this Genevan Psalmody was at once brought into use in England—first (according to a letter of Bishop Jewell to Peter Martyr, dated 5th March 1560) in one London church, from which it quickly spread to others both in London and in other cities. The first edition of the completed "Old Version" appeared in 1562.

In this book, as published in 1562, and for many years afterwards, there were (besides the versified Psalms) eleven metrical versions of the *Te Deum*, canticles, Lord's Prayer (the best of which is that of the *Benedicite*); and also *Da pacem, Domine*, a hymn suitable to the times, rendered into English from Luther; two original hymns of praise, to be sung before morning and evening prayer; two penitential hymns (one of them the "humble lamentation of a sinner"); and a hymn of faith, beginning, "Lord, in Thee is all my trust." In these respects, and also in the tunes which accompanied the words (stated by Dr. Charles Burney, in his *History of Music*, to be German, and not French), there was a departure from the Genevan platform.

Scottish Psalms.—In Scotland, the General Assembly of the kirk caused to be printed at Edinburgh in 1564, and enjoined the use of, a book entitled *The Form of Prayers and Ministry of the Sacraments used in the English Church at Geneva, approved and received by the Church of Scotland; whereto, besides that was in the former books, are also added sundry other prayers, with the whole Psalms of David in English metre*. This contained, from the "Old Version," translations of forty Psalms by Sternhold, fifteen by Whittingham, twenty-six by Kethe and thirty-five by Hopkins. Of the remainder two were by John Pulleyn (one of the Genevan refugees, who became archdeacon of Colchester); six by Robert Pont, Knox's son-in-law, who was a minister of the kirk, and also a lord of session; and fourteen signed with the initials I.C., supposed to be John Craig; one was anonymous, eight were attributed to N., two to M. and one to T. N. respectively.

So matters continued in both churches until the Civil War. During the interval, King James I. conceived the project of himself making a new version of the Psalms, and appears to have translated thirty-one of them—the correction of which, together with the translation of the rest, he entrusted to Sir William Alexander, afterwards earl of Stirling. Sir William having completed his task, King Charles I. had it examined and approved by several archbishops and bishops of England, Scotland and Ireland, and caused it to be printed in 1631 at the Oxford University Press, as the work of King James; and, by an order under the royal sign manual, recommended its use in all churches of his dominions. In 1634 he enjoined the Privy Council of Scotland not to suffer any other psalms, "of any edition whatever," to be printed in or imported into that kingdom. In 1636 it was republished, and was attached to the famous Scottish service-book, with which the troubles began in 1637. When the Long Parliament

undertook in 1642, the task of choosing between the rival translations of the Psalms by Rouse and Barton, Rouse's version was chosen and was received in Scotland with great favour, which it has ever since retained. The "New Version" of the Psalms, by Dr. Nicholas Brady and the poet-laureate Nahum Tate (both Irishmen), appeared in 1696, under the sanction of an order in council of William III. The relative merits of the "Old" and "New" versions have been very variously estimated. Competent judges have given the old the praise, which certainly cannot be accorded to the new, of fidelity to the Hebrew.

Wither, Cosin, Milton and Taylor.—Conspicuous among the sacred poets of the first two Stuart reigns in England was George Wither. His *Hymnes and Songs of the Church* appeared in 1622-1623, under a patent of King James I., by which they were declared "worthy and profitable to be inserted, in convenient manner and due place, into every English Psalm-book to metre." His *Hallelujahs* (in which some of the former *Hymnes and Songs* were repeated) followed in 1641. John Cosin, afterwards bishop of Durham, published in 1627 a volume of "Private Devotions," for the canonical hours and other occasions. The hymns of Milton (on the Nativity, Passion, Circumcision and "at a Solemn Music"), written about 1629, in his early manhood, were probably not intended for singing. During the Commonwealth, in 1654, Jeremy Taylor published at the end of his *Golden Grove*, twenty-one hymns.

Restoration Period.—The epoch of the Restoration produced in 1664 Samuel Crossman's *Young Man's Calling*, with a few "Divine Meditations" in verse attached to it; in 1668 John Austin's *Devotions in the ancient way of offices, with psalms, hymns and prayers for every day in the week and every holiday in the year*; and in 1681 Richard Baxter's *Poetical Fragments*. In these books there are altogether seven or eight hymns, the whole or parts of which are extremely good.

Dryden, Ken, Patrick and Addison.—Dryden's translation of "Veni Creator" a cold and laboured performance, is to be met with in many hymn-books. Abridgments of Ken's morning and evening hymns are in all. These, with the midnight hymn, which is not inferior to them, first appeared in 1697, appended to the third edition of the author's *Manual of Prayers for Winchester Scholars*. Bishop Patrick's hymns were chiefly translations from the Latin, most of them from Prudentius. The best is a version of *Alleluia dulce carmen*.

Of the five attributed to Addison, not more than three are adapted to public singing; one ("The spacious firmament on high") is a perfect and finished composition, taking rank among the best hymns in the English language.

From the preface to Simon Browne's hymns, published in 1720, we learn that down to the time of Dr. Watts the only hymns known to be "in common use, either in private families or in Christian assemblies," were those of Barton, Mason and Shepherd, together with "an attempt to turn some of George Herbert's poems into common metre," and a few sacramental hymns by authors now forgotten, named Joseph Boyse (1660-1728) and Joseph Stennett. Of the 1,410 authors of original British hymns enumerated in Daniel Sedgwick's catalogue, published in 1863, 1,213 are of later date than 1707; and, if any correct enumeration could be made of the total number of hymns of all kinds published in Great Britain before and after that date, the proportion subsequent to 1707 would be very much larger.

The English Independents, as represented by Dr. Isaac Watts, have a just claim to be considered the real founders of modern English hymnody. Watts was the first to understand the nature of the want, and, by the publication of his *Hymns* in 1707-1709, and *Psalms* (not translations, but hymns founded on psalms) in 1709, he led the way in providing for it. His immediate followers were Simon Browne and Philip Doddridge. Later in the 18th century, Joseph Hart, Thomas Gibbons, Miss Anne Steele, Samuel Medley, Samuel Stennett, John Ryland, Benjamin Beddome and Joseph Swain succeeded to them.

Isaac Watts.—Among these writers, most of whom produced some hymns of merit, and several are extremely voluminous, Isaac Watts and Philip Doddridge are pre-eminent.

Of the other followers in the school of Watts, Miss Anne Steele (1717-1778) is the most popular and perhaps the best. The influence of Watts was felt in Scotland, and among the first whom it reached there was Ralph Erskine. This seems to have been after the publication of Erskine's *Gospel Sonnets* which appeared in 1732, five years before he joined his brother Ebenezer in the Secession Church. The *Gospel Sonnets* became as some have said, a "people's classic"; but there is in them very little which belongs to the category of hymnody.

Scottish Paraphrases and Methodist Hymns.—Of the contributions to the authorized "Paraphrases" (with the settlement of which committees of the General Assembly of the Church of Scotland were occupied from 1745, or earlier, till 1781), the most noteworthy, besides the two already mentioned, were those of John Morrison and those claimed for Michael Bruce. The obligations of these "Paraphrases" to English hymnody, already traced in some instances (to which may be added the adoption from Addison of three out of the five "hymns" appended to them), are perceptible in the vividness and force with which these writers, while adhering with a severe simplicity to the sense of the passages of Scripture which they undertook to render, fulfilled the conception of a good original hymn. The "Methodist" movement, which began about 1738, afterwards became divided, between those who esteemed Arminian, under John Wesley, those who adhered to the Moravians, when the original alliance between that body and the founders of Methodism was dissolved, and the Calvinists, of whom Whitfield was the leader, and Selina, countess of Huntingdon, the patroness. Each of these sections had its own hymn-writers, some of whom did, and others did not, secede from the Church of England. The Wesleyans had Charles Wesley, Robert Seagrave and Thomas Olivers; the Moravians, John Cennick, with whom, perhaps, may be classed John Byrom, who imbibed the mystical ideas of some of the German schools; the Calvinists, Augustus Montague Toplady, John Berridge, William Williams, Martin Madan, Thomas Haweis, Rowland Hill, John Newton and William Cowper.

Among all these writers, the palm undoubtedly belongs to Charles Wesley. In the first volume of hymns published by the two brothers are several good translations from the German, believed to be by John Wesley, who, although he translated and adapted, is not supposed to have written any original hymns; and the influence of German hymnody, particularly of the works of Paul Gerhardt, Scheffler, Tersteegen and Zinzendorf, may be traced in a large proportion of Charles Wesley's works.

The Moravian Methodists produced few hymns now available for general use. The best are Cennick's "Children of the heavenly King" and Hammond's "Awake and sing the song of Moses and the Lamb," the former of which (abridged), and the latter as varied by Madan, are found in many hymn-books, and are deservedly esteemed. John Byrom, whose name we have thought it convenient to connect with these, was the author of a Christmas hymn ("Christians awake, salute the happy morn") which enjoys great popularity.

The contributions of the Calvinistic Methodists to English hymnody are of greater extent and value. Few writers of hymns had higher gifts than Toplady, author of "Rock of ages," by some esteemed the finest in the English language.

Berridge, William Williams (1717-1791) and Rowland Hill, all men remarkable for eccentricity, activity and the devotion of their lives to the special work of missionary preaching, though not the authors of many good hymns, composed, or adapted from earlier compositions, some of great merit.

Cowper and Newton.—If, however, the number as well as the quality of good hymns available for general use is to be regarded, the authors of the *Olney Hymns* are entitled to be placed at the head of all the writers of this Calvinistic school. The greater number of the *Olney Hymns* are, no doubt, homely and didactic; but to the best of them, and they are no inconsiderable proportion, the tenderness of Cowper and the manliness of John Newton (1725-1807) give the interest of contrast, as well as that of sustained reality. *The Remains of Henry Kirke White*, published by Southey in 1807, contained a series of hymns, some of which are

still in use; and a few of Bishop Heber's hymns and those of Sir Robert Grant, which, though offending rather too much against John Newton's canon, are well known and popular, appeared between 1811 and 1816, in the *Christian Observer*. In John Bowdler's *Remains*, published soon after his death in 1815, there are a few more of the same, perhaps too scholarlike, character. But the chief hymn-writers of that period were two clergymen of the Established Church—one in Ireland, Thomas Kelly, and the other in England, William Hurn—who both became Nonconformists, and the Moravian poet, James Montgomery (1771-1854), a native of Scotland.

Collections of Hymns.—During this period, the collections of miscellaneous hymns for congregational use, of which the example was set by the Wesleys, Whitfield, Toplady and Lady Huntingdon, had greatly multiplied; and with them the practice (for which, indeed, too many precedents existed in the history of Latin and German hymnody) of every collector altering the compositions of other men without scruple, to suit his own doctrine or taste; with the effect, too generally, of patching and disfiguring, spoiling and emasculating the works so altered, substituting neutral tints for natural colouring, and a dead for a living sense. In the Church of England the use of these collections had become frequent in churches and chapels, principally in cities and towns, where the sentiments of the clergy approximated to those of the Nonconformists.

Two publications, which appeared almost simultaneously in 1827—Bishop Heber's *Hymns*, with a few added by Dean Milman, and John Keble's *Christian Year* (not a hymn-book, but one from which several admirable hymns have been taken, and the well-spring of many streams of thought and feeling by which good hymns have since been produced)—introduced a new epoch, breaking down the barrier as to hymnody which had till then existed between the different theological schools of the Church of England. In this movement Richard Mant, bishop of Down, was also one of the first to co-operate. It soon received a great additional impulse from the increased attention which, about the same time, began to be paid to ancient hymnody, and from the publication in 1833 of Bunsen's *Gesangbuch*. Among its earliest fruits was the *Lyra apostolica*, containing hymns, sonnets and other devotional poems, most of them originally contributed by some of the leading authors of the *Tracts for the Times* to the *British Magazine*; the finest of which is the pathetic "Lead, kindly light, amid th' encircling gloom," by Cardinal Newman—well known, and universally admired. From that time hymns and hymn-writers rapidly multiplied in the Church of England, and in Scotland also. Nearly 600 authors whose publications were later than 1827 are enumerated in Sedgwick's catalogue of 1863, and about half a million hymns are now in existence. Works, critical and historical, upon the subject of hymns, have also multiplied; and collections for church use have become innumerable—several of the various religious denominations, and many of the leading ecclesiastical and religious societies, having issued hymn-books of their own, in addition to those compiled for particular dioceses, churches and chapels, and to books (like *Hymns Ancient and Modern*, published 1861, supplemented 1889, revised edition, 1905) which have become popular without any sanction from authority. Among the best known American hymn-writers are John Greenleaf Whittier, Bishop Doane, Dr. W. A. Muhlenberg and Thomas Hastings; and it is difficult to praise too highly such works as the Christmas hymn, "It came upon the midnight clear," by Edmund H. Sears; the Ascension hymn, "Thou, who didst stoop below," by Mrs. S. E. Miles; two by Dr. Ray Palmer, "My faith looks up to Thee, Thou Lamb of Calvary," and "Jesus, Thou joy of loving hearts," the latter of which is the best among several good English versions of *Jesu, dulcedo, cordium*; and "Lord of all being, throned afar," by Oliver Wendell Holmes.

The more modern "Moody and Sankey" hymns (see Moody, D. L.) popularized a new Evangelical type, and the Salvation Army has carried this still farther.

The object aimed at in this article has been to trace the general history of the principal schools of ancient and modern hymnody, and especially the history of its use in the Christian church. For

this purpose it has not been thought necessary to give any account of the hymns of Racine, Madame Guyon and others, who can hardly be classed with any school, nor of the works of Caesar Malan of Geneva (1787-1864) and other quite modern hymn-writers of the Reformed churches in Switzerland and France.

Otto Kornmüller, *Lexikon der kirchlichen Tonkunst* (1891); F. J. Sillman, *The Story of Our Hymns* (1921); H. E. Langhorne, *Some Favourite Hymns* (1924).

HYNDMAN, HENRY MAYERS (1842-1921), founder of British Socialism, was born in London on March 7, the son of a wealthy man. He was educated at Trinity college, Cambridge and travelled extensively. He was deeply influenced by the Paris Commune and in 1881 joined with several extreme Radicals in forming the London Democratic Federation which advocated views which were practically Socialist. For its first conference (June 1881) he wrote *England for All*, the first Socialist book published in England since the collapse of Owenism. In this he expounded the views of Karl Marx, which he now finally adopted. But as he omitted to make what Marx felt was the necessary acknowledgment of his indebtedness, Marx was offended and Engels who disliked Hyndman deliberately widened the breach. The chief, and indeed only exponent of Marxism in the country where Marx lived was thus not on speaking terms with his leader. This, however, did not stop the spread of Marxist Socialism. The Democratic Federation in 1884 became the Social Democratic Federation and nearly all the prominent Socialists of the new generation, except J. Keir Hardie, were moulded by Hyndman. William Morris, John Burns, Tom Mann, H. H. Champion, George Lansbury and Harry Quelch were among his colleagues and pupils. But it was significant of Hyndman's failings that of these named above only one succeeded in working with him for any long space of time. Hyndman remained always an aristocrat among the Socialists. He was proud and dominant in his manners, intellectually intolerant, and resentful of criticism or disagreement. Even when distributing leaflets announcing meetings he always wore a top hat and frock-coat, and he frequently in Trafalgar square or elsewhere, taunted his ragged audiences with being such fools as to provide the money on which such as he could dress so well. But the qualities of his defects were also present—his indomitable energy which enabled him to create a Socialist movement almost from the void, his self sacrifice and patience, and his uprightness and hatred of compromise and of loose thinking. In the late '80s the Socialist and unemployed movement blew suddenly up to an enormous size; the riots in Trafalgar square were succeeded by the famous dock strike (1889); and for a short while public opinion, hostile or friendly, magnified the importance of the S.D.F. and its leader, whom it credited with the control and inspiration of these occurrences.

With the return of better trade in the '90s the explosive period of Hyndman's career ended, though he incurred plenty of hostility by his denunciation of the Boer War. He was severely critical of the policy of both the Independent Labour Party and the Labour Party, and till 1914 was the acknowledged chief of a small, but hard working and influential party of doctrinaire revolutionaries. But on the outbreak of the World War, to the surprise of his followers, he became a strong nationalist, and later on equally vehement anti-Bolshevik. For the first time he was unable to carry his party with him: in 1915 the British Socialist Party (as it had become) ousted him and his sympathizers from control. They formed a small group known as the "National Socialist Party." He expounded his new views in *The Evolution of Revolution* (1920). He died on November 22, 1921.

See his own *Record of an Adventurous Life* (1911) and *Further Reminiscences* (1912); Mrs. R. T. Hyndman, *The Last Years of H. M. Hyndman* (1923); and F. J. Gould, *Hyndman, Prophet of Socialism* (1928).

HYOGO, a town and district of Japan in the province of Settsu, on the western shore of the bay of Osaka, adjoining the foreign settlement of Kobe, 21 m. W. of Osaka by rail. The growth of its prosperity has been very remarkable. Its population, including that of Kobe, is nearly 1,000,000. Silk and cotton-fabrics and matches are the chief industries.

Hyogo has several temples of interest, one of which has near it a huge bronze statue of Buddha, while by the Minatogawa, which flows into the sea between Hyogo and Kobe, a temple commemorates the spot where Kusunoki Masashige, the mirror of Japanese loyalty, met his death in battle in 1336. The temple of Ikuta was erected on the site of the ancient fane built by Jingo on her return from Korea in the 3rd century.

Hyogo was originally known as Bako and as early as the 12th century was of some maritime importance. (See KOBE.)

HYOSCINE is the chief of the alkaloids (*q.v.*) of *Datura metel*, and is colourless syrup, soluble in most ordinary solvents, and yielding crystalline salts. (Its formula is $C_{17}H_{21}O_4N$.) Of these the hydrobromide, $C_{17}H_{21}O_4N \cdot HBr \cdot 3H_2O$, is that generally used in medicine. It forms colourless rhombs, which melt at 193-194°C. Hyoscine is optically active (*see* STEREOCHEMISTRY), the natural base being laevo-rotatory ($[\alpha]_D^{25} = -18^\circ$ to -28°). It is also known as scopolamine and atropine.

Laevo-hyoscine is easily racemized to *atropine* (compare *atro-pine*) which can be crystallized and yields crystalline salts, usually melting 10-14°C below the corresponding salts of the natural laevo-base. Hyoscine is a mydriatic, like atropine, but is principally used as a sedative in acute mania, and with morphine to produce the so-called "twilight sleep" in maternity cases. Chemically, hyoscine is closely related to atropine.

HYOSCYAMINE, one of the alkaloids (*q.v.*) of belladonna (*q.v.*). It is the chief source of atropine (*q.v.*), to which it stands in the relation of laevo-rotatory optical isomer, being converted to atropine by racemization (*see* STEREOCHEMISTRY). It crystallizes, like atropine, in colourless prisms, has a melting point 108.5°C, a specific rotation $[\alpha]_D^{25} = 22^\circ$, and the chemical formula $C_{17}H_{23}O_3N$. The sulphate forms needles from alcohol, has a melting point 206°C, and is the salt generally used in medicine.

HYPÆTHRUS, an architectural term used by Vitruvius for an opening in the roof to admit light. Alternative forms are hypæthros and hypæthrum. Many students of Greek temples, especially James Fergusson and T. J. Hittorff, basing their conclusions upon the Vitruvian reference to such an hypæthrus in the temple of Zeus Olympius at Athens, and upon coping tiles found in the temple at Aegina, have concluded that all Greek temples had some such method of admitting light. Moreover, late Greek tombs at Cyrene and Delos show raised copings in the centre of the roof as though for such an opening. And according to Strabo (*c.* 50 B.C.), the temple of Apollo Didymæus at Miletus (second half of 4th century B.C.) had its entire vast cella open to the sky and planted with groves of laurel. Pausanias, however, states that this temple was never completed; if this is so a roof may have been planned originally.

The consensus of modern opinion is counter to the idea that the hypæthrus was a common feature. No arrangements for drainage have been found in connection with Greek temples, and the very reference of Vitruvius on which the speculations of Fergusson, Hittorff and others are based seems to point to the arrangement as exceptional enough to warrant mention, and used only in the largest buildings. Thus the ordinary temple would be lighted only by the enormous doorway; certainly light thus obtained would furnish a more beautiful and impressive illumination than any direct glare from above. (T. F. H.)

HYPATIA (A.D. 370?-415), Neoplatonic philosopher, born in Alexandria, was the daughter of Theon, author of a scholia on Euclid and a commentary on the *Almagest*, in which it is suggested that he was assisted by Hypatia. Lecturing in her native city, Hypatia ultimately became the recognized head of the Neoplatonic school there (*c.* 400). Her remarkable intellectual gifts, eloquence and modesty, combined with her beauty, attracted many pupils. Among these was Synesius, afterwards (*c.* 410) bishop of Ptolemais, several of whose letters to her, full of admiration and reverence, are extant. Shortly after the accession of Cyril to the patriarchate of Alexandria in 412, owing to her intimacy with Orestes, the pagan prefect of the city, Hypatia was barbarously murdered (Mar. 415) by a fanatical Christian mob. Socrates (*Hist. Eccl.* vii. 15) has related how she was torn from her chariot, dragged to the Caesareum (then a Christian church), stripped naked, done to death with oyster-shells and finally burnt.

Hypatia, according to Suidas, wrote commentaries on the *Arithmetica* of Diophantus of Alexandria, on the *Conics* of Apollonius of Perga and on the astronomical canon (of Ptolemy), which are now lost. Little is known of her philosophical opinions, but she appears to have embraced the intellectual rather than the mystical side of Neoplatonism, and to have been a follower of Plotinus rather than of Porphyry and Iamblichus.

See Fabricius, *Bibliotheca Graeca* (ed. Harles), ix. 187; John Toland

Tetradymus (1720); R. Hoche in *Philologus* (1860), xv. 435; monographs by Stephan Wolf (Czernowitz, 1879), H. Ligier (Dijon, 1880) and W. A. Meyer (Heidelberg, 1885), who devotes attention to the relation of Hypatia to the chief representatives of Neoplatonism. The story of Hypatia forms the basis of the historical romance by Charles Kingsley (1853).

HYPERBOLA, a geometrical curve; as first conceived, probably by Menaechmus (c. 350 B.C.), a section of an obtuse-angled circular cone made by a plane orthogonal to a cone-element. About 220 B.C. Apollonius generalized the notion into that of a section of any circular cone, made by a plane cutting one element and diverging from the opposite at an angle greater than the vertical, so as to cut also the other nappe of the cone, the double section extending indefinitely both ways without meeting the opposite cone-edge. This is of course indicated in the central rectangular equation of the hyperbola

DIAGRAM OF HYPERBOLA

$$x^2/a^2 - y^2/b^2 = 1,$$

in which, for x (or y) real and infinite (∞), y (or x) is also real and ∞ ; i.e., the curve has two real points at ∞ . This equation of the hyperbola is seen to differ from that of the ellipse only in the sign of b^2 , and accordingly the hyperbola is the counterpart of the ellipse, reflecting its properties, *mutatis mutandis*, although we must suppose the branches continuous through ∞ to detect any likeness in form. Thus (see fig.) the ratio of the distances of any point of the hyperbola from either focus (F, F') and the corresponding directrix (DR), the polar of the pole F , is a constant, the *eccentricity* $e = \sqrt{(a^2 + b^2)/a^2}$, but the changed sign of b^2 makes $e > 1$. Similarly, the difference (not the sum, as in the ellipse) of the focal distances $FP, F'P$ of any point P (x, y) of the hyperbola is a constant, the *transverse axis* is $2a$;

$$F'P - FP = r' - r = 2a.$$

Either of these properties may be taken as a definition of the hyperbola. Again, it is the changed sign of b^2 that marks the two points at ∞ (imaginary in the ellipse) as real in the hyperbola. The tangent and normal still bisect the angles between the focal radii, r, r' , to any point of the hyperbola, but they exchange positions, the tangent lying within, between F and F' , the normal without. Thus, an ellipse and a hyperbola that are confocal intersect orthogonally, a property that extends to confocal conicoids, making possible important orthogonal co-ordinate systems of such surfaces. The ends ($\pm a, 0$) of the transverse axis, AA' , are real, but these ($0, \pm ib$) of its conjugate, BB' , are imaginary in the hyperbola—a relation exactly reversed in the *conjugate* hyperbola

$$x^2/a^2 - y^2/b^2 = -1.$$

In the ellipse, the asymptotes, or tangents at ∞ , are imaginary,

$$x^2/a^2 + y^2/b^2 = 0, \quad x/a = \pm i y/b;$$

but in the hyperbola both are real,

$$x^2/a^2 - y^2/b^2 = 0, \quad x/a = \pm y/b,$$

plainly common to the hyperbola and its conjugate and forming the most striking feature of the curve. The analogue to the circle $x^2 + y^2 = a^2$ in relation to the ellipse, $x^2/a^2 + y^2/b^2 = 1$, is the *rectangular* (equilateral, equiaxial) hyperbola

$$x^2 - y^2 = a^2$$

in relation to $x^2/a^2 - y^2/b^2 = 1$ (both obtained by putting $b=a$). Every other hyperbola is obtained from this, as every ellipse from the circle, by vertical compression (or expansion) in the ratio b/a . On taking the asymptotes, $ay \pm bx = 0$, as coordinate axes, the equation of the hyperbola becomes

$$xy = k^2 = (a^2 + b^2)/4,$$

a simple areal relation that makes the hyperbola the geometric

depiction of various physical phenomena in which two magnitudes vary inversely, their product being a constant, as in $xy = k^2$. By the general law, the equation of the tangent at any point (x', y') is

$$xy' + x'y = 2k^2;$$

hence, for $y=0, x=2k^2/y'$ and for $x=0, y=2k^2/x'$; i.e., the tangent-intercept between the asymptotes is bisected at the tangent-point. Hence the triangle of asymptotes and tangents is constant in area. This tangent-intercept equals the parallel diameter conjugate to the diameter through the tangent-point (P). Obviously the two intercepts ($CA, C'A'$) of any chord (being parallel to a tangent), between the hyperbola and its asymptotes, are equal (see fig.).

HYPERBOLE, a figure of rhetoric whereby the speaker expresses more than the truth, in order to produce a vivid impression; hence, an exaggeration.

HYPERBOLIC FUNCTIONS: see TRIGONOMETRY.

HYPERBOLOID, in geometry, either of two open centric surfaces of the second degree (conicoids, quadrics). The general equation of such centrics takes the form

$$Ax^2 + By^2 + Cz^2 = 1,$$

where A, B, C , may have four orders of signs: $+++$ (ellipsoid), and $---$ (a *nowhere* ellipsoid, with no real points); the other two, $++-$ and $+-$, yield hyperboloids of one nappe or two nappes. The central rectangular equations may be written

$$x^2/a^2 + y^2/b^2 - z^2/c^2 = 1$$

$$\text{and}$$

$$x^2/a^2 - y^2/b^2 - z^2/c^2 = 1$$

FIG. 1

Planes parallel to XY cut the hyperboloid in similar ellipses, $x^2/a^2 + y^2/b^2 = z^2/c^2 + 1$, and the hyperboloid of two nappes in similar hyperbolas

$$x^2/a^2 - y^2/b^2 = z^2/c^2 + 1;$$

likewise for sections parallel to the other coordinate planes. It is simplest to consider the limiting cases, when $a=b=c$. Then hyperboloid

$$x^2 + y^2 - z^2 = a^2$$

is plainly the "revolute" of the rectangular hyperbola $x^2 - z^2 = a^2$ rotated round the Z -axis, each point (x, z) tracing a circle $x^2 + y^2 = a^2 + z^2$. For $z=0$, $x^2 + y^2 = a^2$ becomes minimal circle. The general surface (fig. 1) is found, as in the *ellipsoid* (*q.v.*), by compression (or expansion) of all y 's and z 's in the ratios b/a and c/a respectively, which yields $x^2/a^2 + y^2/b^2 - z^2/c^2 = 1$. The "revolute" has as tangent at ∞ the central cone $x^2 + y^2$

$-z^2 = 0$, which remains tangential in the form $x^2/a^2 + y^2/b^2 - z^2/c^2 = 0$, after the affine transformation. Rotating the same hyperbola $x^2 - z^2 = a^2$ round X yields the *conoid* $x^2 - y^2 - z^2 = a^2$, whose asymptotic cone is $x^2 - y^2 - z^2 = 0$. On compression (or expansion) parallel to Y or Z in the ratio $b/a, c/a$ respectively, there results the general hyperboloid of two nappes $x^2/a^2 - y^2/b^2 - z^2/c^2 = 1$, with its asymptotic cone $x^2/a^2 - y^2/b^2 - z^2/c^2 = 0$ (fig. 2).

Surfaces of second degree are all *ruled*, i.e., traceable by a right line moving in a definite way. For, combining the two equations of a line and the one of such a surface, we may eliminate two

FIG. 2

coordinates and obtain a resultant equation in one coordinate, and this equation, which is of the second degree, vanishes identically when its three coefficients reduce each to 0; and since the equations of the line have four parameters, this reduction is possible in an ∞ of ways; hence there are ∞ many lines lying on a conicoid, like line-elements forming a cone. In the ellipsoid and the hyperboloid of two nappes these lines are imaginary, but in the hyperboloid of one nappe they are real, forming two systems, each line of each system meeting all lines of the other system but none of its own (fig. 3). See MATHEMATICAL MODELS.

HYPERBOREANS, a mythical people intimately connected with the worship of Apollo, especially but not exclusively that at Delos (*Ἰπέρβόρειοι*, *Ἰπέρβόρειοι*). Their names do not occur in Homer, but Herodotus (iv. 32) states that they were mentioned in Hesiod and in the *Epigoni*, an epic of the Theban cycle. According to Herodotus, two maidens, Opis and Arge, and later two others, Hyperoche and Laodice, escorted by five men, called by the Delians Perpherees, were sent by the Hyperboreans with certain offerings to Delos. Finding that their messengers did not return, the Hyperboreans adopted the plan of wrapping the offerings in wheat-straw and requested their neighbours to hand them on to the next nation, and so on until they finally reached Delos. The likeliest explanation of their name is still that of H. L. Ahrens. They are "those who carry over" (*βόρ- = φέρ-* in Macedonian and other Northern speeches, and may be thus connected with *φέρω*). The name then refers to the bringing of the offerings; *ἰπέρβόρειοι* and *περφερέες* are probably the same. It is, of course, likely enough that an Apollo-worshipping people or clan really lived in the north; the offerings must have come from somewhere.

Under the influence of a derivation from *βορέας*, the home of the Hyperboreans was placed in a paradisiacal region beyond the north wind. The duration of their life was 1,000 years, but if any desired to shorten it, he decked himself with garlands and threw himself from a rock into the sea. The close connection of the Hyperboreans with the cult of Apollo may be seen by comparing the Hyperborean myths, the characters of which by their names mostly recall Apollo or Artemis (Agyieus, Opis, Hecargos, Loxo), with the ceremonial of the Apolline worship.

See O. Crusius in Roscher's *Lexikon*, O. Schröder in *Archiv für Religionswissenschaft* (1904), viii. 69; W. Mannhardt, *Wald-und Feldkulte* (1905); L. R. Farnell, *Cults of the Greek States* (1907), iv. 100.

HYPEREIDES (c. 390–322 B.C.), one of the ten Attic orators, was the son of Glaucippus, of the deme of Collytus. Having studied under Isocrates, in 360 he prosecuted Autocles, a general charged with treason in Thrace (frags. 55–65, Blass). At the time of the Social War (358–355) he accused Aristophon, then one of the most influential men at Athens, of malpractices (frags. 40–44, Blass), and impeached Philocrates (343) for high treason. From the peace of 346 to 324 Hypereides supported Demosthenes in the struggle against Macedon; but in the affair of Harpalus he was one of the ten public prosecutors of Demosthenes, and on the exile of Demosthenes he became the head of the patriotic party (324). He was the chief promoter of the Lamian war against Antipater and Craterus, and after the defeat at Crannon (322), Hypereides and the other orators, whose surrender was demanded by Antipater, were condemned to death. Hypereides fled to Aegina, but Antipater's emissaries dragged him from the temple of Aecus, where he had taken refuge, and put him to death; according to others, he was taken before Antipater at Athens or Cleonae. His body was afterwards removed to Athens. Hypereides was an ardent pursuer of "the beautiful"; his temper was easy-going and humorous. In his development of the

FIG. 3

periodic sentence he followed Isocrates, but the essential tendencies of his style are those of Lysias, whom he surpassed, however, in the richness of his vocabulary and in the variety of his powers. His diction was plain and forcible, and his composition simple. Jebb sums up the criticism of pseudo-Longinus (*De sublimitate*, 34) in the phrase—"Hypereides was the Sheridan of Athens."

Most of what we possess of Hypereides's speeches was discovered in the second half of the 19th century, and edited by Sir Frederick Kenyon (1893).

On Hypereides generally see pseudo-Plutarch, *Decem oratorum vitae*; F. Blass, *Attische Beredsamkeit*, iii.; R. C. Jebb, *Attic Orators*, ii. 381. A full list of editions and articles is given in F. Blass, *Hyperidis orationes sex cum ceterarum fragmentis* (1894, Teubner series), to which may be added I. Bassi, *Le Quattro Orazioni di Iperide* (introduction and notes, 1888), and J. E. Sandys in *Classical Review* (Jan. 1895) (a review of the editions of Kenyon and Blass). For the discourse against Athenogenes see H. Weil, *Études sur l'antiquité grecque* (1900).

HYPERGAMY. The custom of hypergamy forbids a woman of a particular group to marry a man of a group lower than her own in social standing. When, as in India, severe social penalties support this rule, it produces serious effects upon the social order. It allows men to marry women of groups below them and therefore favours the men. It reinforces social distinctions and flourishes in societies where these are numerous, permanent and of the essence of the social order. It restricts the field of marriage in the case of the women of the highest section. It is found in its extreme development in India within castes which are divided into sections based on differences of religious purity, social eminence, political authority or economic superiority. To it are traced female infanticide (q.v.), the purchase of husbands, and wholesale polygamy.

The same principle is at work in the cases where, as in Africa, a community has been formed by the dominance of a group of alien origin of different physique imbued with a strong sense of superiority. Women from the inferior conquered subordinate classes are accepted as mates by the ruling class, which does not allow its women to mate with males of the subject people. King Cophetua may wed the beggar-maid, but the princess makes a misalliance.

Crooke, 1915); Sir Arthur Keith, *Nationality and Race* (1919); John Roscoe, *The Bakitara* (1923); C. K. Meek, *The Northern Tribes of Nigeria* (1925); C. C. North, *Social Differentiation* (1926).

HYPERION, in Greek mythology, one of the Titans, son of Uranus and Gē, and father of Helios, the sun-god (Hesiod, *Theog.*, 134, 371). The name is often used as an epithet of Helios, who is himself sometimes called simply Hyperion. Its meaning may be "son of Hyperos"; i.e., of him who is above (heaven).

HYPERSTHENE, a rock-forming mineral belonging to the group of orthorhombic pyroxenes. It differs from the other members (enstatite and bronzite) of this group in containing a considerable amount of iron replacing magnesium; the chemical formula is (Mg,Fe)SiO₃. Distinctly developed crystals are rare, the mineral being usually found as foliated masses embedded in those igneous rocks—norite, hypersthene-andesite, etc.—of which it forms an essential constituent. The coarsely grained labradorite-hypersthene-rock (norite) of St. Paul island, Labrador, has furnished the most typical material. The colour is brownish-black, and the pleochroism strong; the hardness is 6 and specific gravity 3.4–3.5.

HYPERTROPHY, a term in medicine implying increase in size of an organ or component tissue of the body, where such enlargement involves the natural elements of the part and is not the result of the presence of some extraneous morbid material. Thus, a lung in pneumonia, a liver full of cancer, is enlarged but not hypertrophied. Further, the word implies life, an uncut nail or excessive length of hair is not hypertrophy. The enlargement may consist in the presence of a normal number of elements each of excessive size (true hypertrophy) or an excessive number of elements, each of normal size (hyperplasia). Frequently both conditions are present.

Hypertrophy may be physiological or pathological. Physiological hypertrophy is due either to work (e.g., the muscles of an athlete), or is compensatory (e.g., when one of paired organs is absent or removed). For hypertrophy to occur the functional

activity demanded must be well within its powers, otherwise atrophy occurs. Pathological hypertrophy is seen in leucocythæmia, where the spleen is enormously enlarged; lymphadenoma, where lymphatic glands are enlarged; acromegaly, where bone is affected, etc. Physiological hypertrophy occurs under pathological conditions. The hypertrophy of the left ventricle in aortic obstruction, of the bladder in stricture of the urethra, of the stomach in pyloric obstruction are examples of work hypertrophy.

The causes of hypertrophy are largely the converse of those causing atrophy (*q.v.*), but as is shown by acromegaly, endocrine activity plays a part not observed in atrophy, and the growth of tissues in dermoid cysts or in monsters without brain or spinal cord (*see MONSTERS*) is clearly independent of the nervous system. As hypertrophy is essentially growth carried beyond normal limits the conditions underlying it are those underlying growth. These are (1) an inherent power of growth on the part of the cell; (2) an excessive supply of nutriment; (3) a stimulus.

A spurious hypertrophy is observed in the rare disease *pseudo-hypertrophic muscular paralysis*, in which the calves, buttocks and muscles of the back are greatly enlarged but excessively feeble. The enlargement is due to interpolation of fatty connective tissue between the muscular bundles which themselves are greatly atrophied. (W. S. L.-B.)

HYPNOTISM, a term involving all that appertains to that condition of artificial sleep known as hypnosis which is allied to normal sleep and can be induced in many normal persons. At all times individuals have fallen into an abnormal state of mind resembling the hypnotic state, such a condition being deliberately induced by others, through their own efforts, or spontaneously arising, generally under the influence of some special emotional excitement. Hypnotic phenomena were known thousands of years ago to the Persian magi and the Indian yogis and fakirs but scientific and medical interest in the subject was first universally aroused during the latter part of the 18th century by the work of Mesmer, a Viennese physician, who claimed to be able to cure many diseases by means of "animal magnetism." He enunciated the doctrine of a vital magnetic fluid which became stored up in living bodies, and by its instrumentality one individual could act on another. This method of mesmerism, notwithstanding much remedial success, was adversely reported on by several scientific commissions so that it fell into disuse until a generation later, when interest in it as a form of medical treatment was revived, but unfortunately mingled with much charlatanism.

In the middle of the 19th century Braid, a Manchester surgeon, recognized its validity but denied any magnetic element. He became convinced that there was no mysterious fluid passing from operator to subject, that the phenomena elicited were really subjective in origin, and it was he who first used the term "hypnotism" in place of mesmerism and laid the foundations for its modern study. Before many years the method was practised by physicians in all European countries. Liébault and Bernheim, at Nancy, laid the foundation of the school of hypnotic suggestion which has since held sway. In the hands of such investigators as Pierre Janet much light has been thrown by hypnotic experimental work on the constitution of the mind.

Methods of Induction.—The usual modern procedure is to place the subject in an arm-chair or on a couch where there shall be absolute muscular relaxation and passivity of mind. The environment should be conducive to sleep. The physician, standing at the side, holds up the index and middle fingers of one hand, a little above and away from the patient's eyes. The gaze is fixed on these and verbal suggestions are made to the effect that the eyelids are getting heavy, drowsiness is being felt, the eyes are closing, and sleep approaches. Light sensory stimulation by stroking the forehead gently or making downward passes over the face may also be carried out. In many subjects the eyelids gradually flicker more and more and then close as some stage of sleep supervenes. Self-induction of hypnosis may be possible by fixation of gaze in some people who have previously been hypnotized by another. Repeated hypnotic sitting commonly renders the advent of sleep easier. In specially susceptible patients complete hypnosis may supervene at once on the command to sleep either made

orally or in writing. Terminating hypnosis is easily brought about by suggesting the idea of wakefulness, but if left to themselves patients, after a variable time, would spontaneously resume the normal state.

Different stages of hypnosis have been described by different authorities, many of them being very artificial, but it will suffice if we speak of three only. In very light hypnosis there is complete passivity and relaxation with an inability to open the eyes or resist some simple commands concerning the voluntary muscles. The individual is quite conscious of all that goes on. In a further stage, further phenomena can be produced, but still there is recollection of the hypnotic period. The most susceptible subjects may pass into a deep sleep known as artificial somnambulism. Here they respond to all or most suggestions made by the operator, and on awakening are oblivious to all they have heard, said, or done while in that state.

Hypnosis in some stages can be induced in a large percentage of normal people provided that they willingly submit to the process. Soldiers from active service during the World War were almost universally found easy subjects. For definite psychological reasons the insane are usually impervious to its influence.

Signs and Symptoms Seen in Hypnosis.—A peculiar relationship exists between patient and operator in the deep stages. They are said to be "en rapport"; only suggestions from the latter are accepted. Suggestibility is much increased though there are limitations to what suggestions will be acted upon. As already stated, the memory of the sleep period in deep hypnosis is lost, but this so-called amnesia can be much modified by suggestions. During hypnosis there is a great widening of the memory so that impressions long since forgotten can be revived. Much use of this phenomenon is made in treatment of various abnormalities. Suggestions made during hypnosis may be carried out subsequently to waking, and at a definitely named hour. This post-hypnotic suggestion is highly important in that it demonstrates the unconscious calculation of time and also shows that actions may be carried out without awareness of the source of the impulse. Through suggestion under hypnotism the voluntary muscles may be paralysed or put in a state of tonic contraction, and also the action of involuntary muscular fibre modified so that arterial blood flow and bowel movement can be to some extent controlled. The special senses tend to be rendered more acute, feeling and pain can often be abolished, and positive and negative hallucinations brought about. After repeated hypnosis many of these phenomena can be elicited even in the waking state by suggestion.

Possible Dangers.—The possible dangers of hypnotism have been much exaggerated, and in the hands of an expert physician no fear need be felt. Repeated hypnosis in certain types will tend to increase a mental dissociation which already exists, and there is apt to arise a far too great dependency on the operator. Whether criminal action can be suggested is a debatable point, but it may be stated that there is good reason for believing that no hypnotized subject will follow a suggestion which is contrary to his fundamental personal character.

The practice of hypnotism as a method of medical treatment has now largely been relinquished and superseded by other forms of psychotherapy. It is a blind method of procedure in that the origin of any disorder is not thereby usually traced, and attacking the cause of illness and not its surface manifestation should always be our scientific aim. Its use has been mainly applied to the treatment of the so-called functional nervous diseases, and in these states of mental disharmony modern knowledge has placed physicians in a position to unravel the causation links by some analytical means. Nevertheless, hypnotic suggestion in appropriate cases has its distinct sphere of usefulness. It may also be employed for the amelioration of pain, insomnia, stammering, seasickness, etc.

Theories Regarding Hypnosis.—Various theories of hypnosis have been propounded, and it may be viewed from both a physiological and psychological aspect. The factor of any magnetic or other power on the part of the operator has been long discarded, and that the phenomenon is subjective and due to suggestion is now more or less universally held. Charcot regarded

it as a form of artificial hysteria, and there are undoubted links between the two conditions. Modern authorities would explain it in terms of mental dissociation. In ordinary sleep it is presumed that the different nerve cells in the higher parts of the brain are dissociated from each other, and it may be that in hypnosis there is the same relative dissociation but that through the presence of the operator and the special link which exists between him and the subject one part of the nervous system is kept active and awake. Because the rest of the brain is quiescent, no contrary ideas are aroused to prevent the acceptance of suggestions which are therefore acted upon immediately. The psycho-analytic school would base the explanation of this artificial sleep and suggestibility on the idea that the operator symbolically represents the parent in the mind of the subject and that there is therefore an unconscious attitude of blind belief and obedience to the suggestions that may be made. The special rapport existing between the two would be thus interpreted.

It must not be forgotten that experimental work in hypnotism has been highly fruitful in adding to our knowledge of normal and abnormal psychology. Through its phenomena we are enabled better than in any other way to demonstrate the process of unconscious motivation, and to see in the mind the probability of a series of levels at which different mental processes take place.

(C. S. R.)

HYPOCAUST, in architecture, an open space below a floor to allow the passage of hot air and smoke, in order to heat the room above. This type of heating was developed to a high degree by the Romans who used it, not only in the warm and hot rooms of the baths (*q.v.*), but also almost universally in private houses in the northern provinces. Many examples of such hypocausts exist in villa and house foundations in Roman centres in Germany and England. Although the usual custom was to lead the smoke from a hypocaust into a single vertical flue through which it escaped into the open air, where greater warmth was desired, several flues would lead up from the hypocaust in the side walls of the room; at times, these wall flues consisted of hollow oblong tiles, set close together, entirely around the room. The usual construction of a hypocaust consisted of a layer of tiles, 2 ft. square, laid continuously in a bed of concrete for the bottom surface, piers approximately 8 in. square and about 2 ft. apart as the supports, and a floor above of concrete or of large square tiles supporting a bed of concrete, on which the finished floor of marble, tesserae or mosaic was laid.

HYPOCHONDRIASIS, a medical term, given by the ancients and early physicians to derangements of the abdominal viscera. It is not now used to refer to any actual disease but to a morbid mental symptom which consists in an undue pre-occupation in one's own state of health with a tendency to find evidence of disease from insignificant signs. There may arise a settled conviction that disease exists even in their absence. The idea of ill-health, however, relates essentially to the internal organs and predominantly to the functioning of the heart, intestinal canal, or genital structures. Such a symptom may occur in many forms of mental illness. It is not infrequently noted in hysterical anxiety and neurasthenic neuroses; in melancholic states, especially those of later years; in dementia praecox; and in the initial stages of such organic psychoses as arterio-sclerotic dementia and general paresis.

In some cases hypochondriasis seems to present itself without any other symptom, and though examination reveals no physical abnormality, the assurance of that fact has usually only a temporary effect on the false belief which may lead to self-centredness, depression and insomnia.

It is probable that the hypochondriacal type has a greater sensitivity to sensations emanating from the internal organs, is therefore more easily aware of any change that may occur therein, and so more affected by any possible alteration in their functioning.

Any treatment naturally depends on the associated disease. In its more pure manifestation some form of psychotherapy is

indicated, but results are often disappointing. (C. S. R.)

HYPOSTYLE, in architecture, a term applied to halls with flat ceilings supported by columns, especially in Egyptian work. A hypostyle hall formed the largest room in every Egyptian temple. It was usually placed immediately behind the main court and in front of the small rooms that formed the sanctuary. Such halls were either lit by openings between the front range of columns, above the low screen wall built between them, as in the Ptolemaic temple at Edfu (237 to 57 B.C.), or by having the central ranges of columns taller than those at the side so that a clerestorey of pierced stone screens was possible above the roof of the side portions.

HYPOSULPHITE OF SODA, the name originally given to the salt, still in general use by photographers as a fixing agent, known in chemistry as sodium thiosulphate, $\text{Na}_2\text{S}_2\text{O}_3$. One molecule of the salt crystallizes with five molecules of water. In systematic chemistry sodium hyposulphite is a salt of hyposulphurous acid, to which Schutzenberger gave the formula H_2SO_2 , but which Bernthsen showed to be $\text{H}_2\text{S}_2\text{O}_4$. (See SULPHUR; and HYDROSULPHITE OF SODA.)

HYPOTHEC, in Roman law, the most advanced form of the contract of pledge. A specific thing may be transferred to the possession of a creditor on the condition that it is to be given back when the debt is paid; or the property in the thing may be assigned to the creditor while the debtor is allowed to remain in possession, the creditor as owner being able to take possession if his debt is not discharged. Here we have the kind of security known as pledge and mortgage respectively. In the hypothec the property does not pass to the creditor, nor does he get possession, but he acquires a preferential right to have his debt paid out of the hypothecated property; that is, he can sell it and pay himself out of the proceeds, or in default of a purchaser he can become the owner himself. The name and the principle have passed into the law of Scotland, but the number of instances in which movable property may be hypothecated is restricted to a few cases under the heads of (1) landlord and tenant (*q.v.*), (2) agent and client, (3) maritime hypothecs and (4) privileged debts. A law agent has a hypothec for his amount of expenses incurred in an action over his client's right contained in a furnishing of expenses due to the client from his opponent, which failing, over any principal sum declared for in the client's favour. In maritime hypothecs the ship may be hypothecated for (a) bottomry loans, (b) repairs executed abroad, (c) seamen's wages, and (d) collisions and salvage. A debtor's personal estate also is subject to hypothecs (a) in favour of the claim for unpaid taxes, (b) in favour of domestic and farm servants for their current wages and (c) where the debtor has died, in favour of his medical attendant for death-bed and funeral expenses, in favour of his widow for mournings, and in favour of his landlord for the current rent of his dwelling house.

HYPOTHESIS, in ordinary language, a tentative explanation, supposition or assumption (from Gr. *ὑποτιθέναι*, to put under; Lat. *suppositio*, from *sub-ponere*). Both in ordinary life and in the acquisition of scientific knowledge hypothesis is all-important. A detective's work consists largely in forming and testing hypotheses. If an astronomer is confronted by some phenomenon which has no obvious explanation he may suppose some set of conditions which might give rise to the phenomenon in question; he then tests his hypothesis until he discovers whether it does or does not conflict with the facts. An example of this process is that of the discovery of the planet Neptune: certain perturbations of the orbit of Uranus had been observed, and it was seen that these could be explained on the hypothesis of the existence of a then unknown planet, and this hypothesis was verified by actual observation. The progress of inductive knowledge is by the formation of successive hypotheses, and it frequently happens that the demolition of one or even many hypotheses is the direct road to an accurate hypothesis, *i.e.*, to knowledge.

The recognition of the importance of hypotheses has led to various attempts at drawing up exact rules for their formation, but logicians are generally agreed that only very elementary principles can be laid down. Thus a hypothesis must contain

nothing which is at variance with known facts or principles: it should not postulate conditions which cannot be verified empirically. J. S. Mill (*Logic*, III. xiv. 4) laid down the principle that a hypothesis is not "genuinely scientific" if it is "destined always to remain a hypothesis": it must "be of such a nature as to be either proved or disproved by comparison with observed facts." Mill's principle, though sound in the abstract, has, except in a few cases, little practical value in determining the admissibility of hypotheses, and in practice any rule which tends to discourage hypothesis is undesirable. The most satisfactory check on hypothesis is expert knowledge in the particular field of research by which rigorous tests may be applied. This test is roughly of two kinds, first by the ultimate principles or presuppositions on which a particular branch of knowledge rests, and second by the comparison of correlative facts. Useful light is shed on this distinction by Lotze, who contrasts (*Logic*, § 273) *postulates* ("absolutely necessary assumptions without which the content of the observation with which we are dealing would contradict the laws of our thought") with *hypotheses*, which he defines as conjectures, which seek "to fill up the postulate thus abstractly stated by specifying the concrete causes, forces or processes, out of which the given phenomenon really arose in this particular case, while in other cases maybe the same postulate is to be satisfied by utterly different though equivalent combinations of forces or active elements." Thus a hypothesis may be ruled out by principles or postulates without any reference to the concrete facts which belong to that division of the subject to explain which the hypothesis is formulated. A true hypothesis, therefore, seeks not merely to connect or colligate two separate facts, but to do this in the light of certain fundamental principles.

(See LOGIC; SCIENTIFIC METHOD; SYLLOGISM.)

See Naville, *La Logique de l'hypothèse* (1880); A. Wolf, *Essentials of Scientific Method* (1928).

HYPOTRACHELIUM, in architecture, the space which lies between the annulets or little rings at the bottom of the echinus or convex portion of the Greek Doric capital, and the topmost stone of the column shaft proper. It is thus the lowest portion of the stone from which the capital is carved, and contains the tops of the column flutes. It is frequently decorated at the bottom by a groove or grooves circling the circumference, which may have inserted mouldings of bronze. The word is also sometimes applied in the Roman Doric order to the necking, or space between the bottom of the capital and the astragal, or convex moulding, with fillet below which marks the top of the shaft proper (see ORDER).

HYPOTROCHOID: see CURVES, SPECIAL.

HYPSONETER, an instrument for measuring heights (Gr. *ψῦος*, height, *μέτρον*, a measure), which employs the principles that the boiling-point of a liquid is lowered by diminishing the pressure (see HEAT) and that the barometric pressure varies with the height of the point of observation. (See METEOROLOGY.) The instrument consists of a cylindrical vessel in which the liquid, usually water, is boiled, surmounted by a jacketed column, in the outer partitions of which the vapour circulates, while in the central one a thermometer is placed.

HYRACOIDEA, a group of small hoofed mammals, including the biblical cony. The name cony or coney originally referred to the rabbit but has also come to be used for the related pikas, and for the present quite distinct animals. There is no unambiguous popular term for members of the Hyracoidea. They are usually called hyraxes (or hyraxes). "Rock rabbits," also sometimes used, is objectionable because they are not rabbits and many of them have nothing to do with rocks. In appearance the living hyraxes, with their plump, pointed heads, short necks, relatively short, slender legs, and squat, almost tailless bodies, look much more like rodents than ungulates. Nevertheless their anatomy clearly shows they are related to the hoofed mammals.

Living hyraxes are confined to Africa south and east of the Sahara and extreme southwestern Asia. They may be divided into two groups. One, the genus *Procavia*, includes the ground-living forms, especially characteristic of deserts, hills and mountains up to about 10,000 feet, living in holes and fissures among

the rocks. The other group is similar but is best separated as *Dendrohyrax*. These forms, confined to Africa, are almost entirely tree-dwelling, the only true arboreal hoofed mammals. They live in holes in trees and move readily along the trunks and branches. Both types climb easily, clinging even to almost vertical surfaces by the pads on their feet.

The hyraxes have numerous structural peculiarities which separate them sharply from any other mammals. The normal adult

dental formula is $I \frac{1}{2} C \frac{0}{0} P \frac{4}{4} M \frac{3}{3}$. The upper incisors are large,

curved in a semicircle longitudinally, and grow continuously throughout life like those of rodents. Canines are absent. The premolars and molars are in pattern surprisingly like those of some of the typical ungulates, especially the rhinoceros. The dorsal and lumbar vertebrae are unusually numerous (up to 30 in *Procavia*). On both front and hind feet the three middle toes are well-developed. In the forefeet the other two toes are also present, although the first is much reduced; in the hind feet the first toe is absent, the fifth vestigial. The hoof of the inner (second) toe of the hind foot is claw-like, but on all the other toes the hooves are normal, although small. The wrist-bones are arranged serially, the individual bones generally coming in contact with only one bone of the opposite row—an arrangement typical of the most primitive extinct ungulates but lost in the more specialized modern forms. The alimentary canal is unique in having a pair of large coeca opening into the large intestine some distance below the usual one at the junction of large and small intestines. There is a gland on the back.

The relationships of the hyraxes are doubtful. There is no question that the numerous resemblances to the rodents are all superficial and that the fundamental characters indicate affinities with the ungulates, but these affinities must be distant so far as any living forms are concerned. In addition to their many very primitive characters, the hyraxes show some special resemblance to primitive or extinct members of several groups, particularly the Proboscidea, Perissodactyla, some Condylarthra (*Meniscotherium*), and the peculiar South American fossil ungulates. This confusing series of resemblances suggests that the group is an ancient and unprogressive offshoot derived from the ungulate stem at a time when the modern groups of ungulates were not well differentiated.

Fossil Hyracoidea.—Numerous extinct hyracoids are known and they indicate that the group was formerly much more diversified than at present. Ten extinct genera are recognized, chiefly from the Oligocene of Egypt (Faiyum), Miocene of east and southwest Africa, and Pliocene of Greece (Pikermi and Samos). The earliest forms are characterized generally by having a full

complement of teeth, $I \frac{2}{3} C \frac{1}{1} P \frac{4}{4} M \frac{3}{3}$, with the last molars rela-

tively larger than in recent forms. In some cases, for instance *Geniohyus* from Faiyum, the skull was strikingly elongated. Most of these extinct forms were larger than the recent hyraxes and some, such as species of *Megalohyrax* or *Titanohyrax* from Faiyum or *Pliohyrax* from Greece, were relatively gigantic. The largest must have been as big as a horse. (See UNGULATA.)

(G. G. SI.)

HYRAX, the name given to animals of the order Hyracoidea, small, plump, almost tail-less beasts, having a hoof on each toe, superficially resembling rodents but forming an order of their own of doubtful affinities. Here belongs the "cony" of the Bible. There are two genera, *Procavia*, which comprises the ground-living forms (including the "cony"), and *Dendrohyrax*, the species of which are arboreal. *Procavia* is distributed over Africa, south and east of the Sahara, and south-western Asia; *Dendrohyrax* is confined to Africa. All hyraxes climb well. *Procavia* is found in deserts and mountainous country, living in holes among rocks.

HYRCANIA. (1) An ancient district of Asia, south of the Caspian Sea, and bounded on the east by the river Oxus, called *Virkana*, or "Wolf's Land," in Old Persian. It was a wide and indefinite tract. Its chief city is called Tape by Strabo, Zadracarta by Arrian. The latter is evidently the same as Carta, mentioned by Strabo as an important city. Little is known of the history of

the country. Xenophon says it was subdued by the Assyrians; Curtius that 6,000 Hyrcanians were in the army of Darius III. (2) Two towns named Hyrcania are mentioned, one in Hyrcania, the other in Lydia. The latter is said to have derived its name from a colony of Hyrcanians, transported thither by the Persians.

HYRCANUS (*Ἰρκανός*), a Greek surname, of unknown origin, borne by several Jews of the Maccabean period.

JOHN HYRCANUS I., high priest of the Jews from 135 to 105 B.C., was the youngest son of Simon Maccabaeus. In 137 B.C. he, with his brother Judas, commanded the force which repelled the invasion of Judaea led by Cendebeus, the general of Antiochus VII. *Sidetes*. On the assassination of his father and two elder brothers by Ptolemy, governor of Jericho, his brother-in-law, in 135, he succeeded to the high priesthood and the supreme authority in Judaea. While still engaged in the struggle with Ptolemy, he was attacked by Antiochus with a large army (134), and compelled to shut himself up in Jerusalem. Peace was secured at last on condition of a Jewish disarmament, and the payment of an indemnity and an annual tribute. He confirmed the alliance which his father had made with Rome, and at the same time availed himself of the weakened state of the Syrian monarchy under Demetrius II. to overrun Samaria, and also to invade Idumaea, which he completely subdued. About 109 B.C. his sons took Samaria, and by his orders razed it to the ground. He died in 105, and was succeeded by Aristobulus, the eldest of his five sons. The external policy of Hyrcanus was marked by considerable energy and tact, and, aided by favouring circumstances, was so successful as to leave the Jewish nation in a position of great independence and influence.

JOHN HYRCANUS II., high priest from 78 to 40 B.C., was the eldest son of Alexander Jannaeus by his wife Alexandra, and was thus a grandson of the preceding. When his father died in 78, he was appointed high priest, and on his mother's death in 69 he claimed the succession to the supreme civil authority. After a troubled reign of three months, he was compelled to abdicate both dignities in favour of his more ambitious younger brother Aristobulus II. In 63 Pompey restored him to the high priesthood, with some semblance of supreme command. He was soon again deprived of his office by the arrangement of the pro-consul Gabinius, according to which Palestine was in 57 B.C. divided into five separate circles. For services to Caesar after the battle of Pharsalia, he was again rewarded with the sovereignty in 47 B.C., Antipater of Idumaea, however, being at the same time made procurator of Judaea. In 41 B.C. he was practically superseded by Antony's appointment of Herod and Phasael to be tetrarchs of Judaea; and in the following year he was taken prisoner by the Parthians, deprived of his ears that he might be permanently disqualified for priestly office, and carried to Babylon. He was permitted in 33 B.C. to return to Jerusalem, where on a charge of treasonable correspondence with Malchus, king of Arabia, he was put to death in 30 B.C.

See Josephus (*Ant.* xiii. 8-10, xiv. 5-13; *Bell. Jud.* i. 2, i. 8-13). Also MACCABEES, *History*.

HYSSOP (*Hyssopus officinalis*), a garden herb belonging to the family Labiatae, formerly cultivated for use in domestic medicine. It is a small perennial plant about 2 ft. high, with slender, quadrangular, woody stems; narrowly elliptical, pointed, entire, dotted leaves, about 1 in. long and $\frac{1}{2}$ in. wide, growing in pairs on the stem; and long terminal, erect, half-whorled, leafy spikes of small violet-blue flowers, which are in blossom from June to September. Varieties of the plant occur in gardens with red and white flowers, also one having variegated leaves. The leaves have a warm, aromatic, bitter taste, and are believed to owe their properties to a volatile oil which is present in the proportion of $\frac{1}{4}$ to $\frac{1}{2}$ %. Hyssop is a native of the south of Europe, its range extending eastward to central Asia, and has become naturalized in North America from Maine to Ontario and southward and also on the Pacific coast. A strong tea made of the leaves, and sweetened with honey, was formerly used in pulmonary and catarrhal affections, and externally as an application to bruises and indolent swellings.

The hedge hyssop (*Gratiola officinalis*) belongs to the family

Scrophulariaceae, and is a native of marshy lands in the south of Europe, whence it was introduced into Great Britain more than 300 years ago. Like *Hyssopus officinalis*, it has smooth, opposite, entire leaves, but the stems are cylindrical, the leaves twice the size, and the flowers solitary in the axils of the leaves and having a yellowish-red veined tube and bluish-white limb, while the capsules are oval and many-seeded. The herb has a bitter, nauseous taste, but is almost odourless. In small quantities it acts as a purgative, diuretic and emetic when taken internally. It is said to have formed the basis of a celebrated nostrum for gout, called *Eau médicinale*, and in former times was called *Gratia Dei*. When growing in abundance, as it does in some damp pastures in Switzerland, it becomes dangerous to cattle. *G. peruviana* is known to possess similar properties.

The hyssop (*'ezob*) of Scripture (Exod. xii. 22; Lev. xiv. 4, 6; Num. xix. 6, 18; 1 Kings v. 13 [iv. 33]; Ps. li. 9 [7]; John xix. 29), a wall-growing plant adapted for sprinkling purposes, has long been the subject of learned disputation, the only point on which all have agreed being that it is not to be identified with the *Hyssopus officinalis*, which is not a native of Palestine. No fewer than eighteen plants have been supposed by various authors to answer the conditions. The most probable opinion would seem to be that found in Maimonides and many later writers, according to which the Hebrew *'ezob* is to be identified with the Arabic *sa'atar*, now understood to be *Satureia Thymus*, a plant of very frequent occurrence in Syria and Palestine, with which *Thymus Serpyllum*, or wild thyme, and *Satureia Thymbra* are closely allied. Its smell, taste and medicinal properties are similar to those of *H. officinalis*.

HYSTASPES (the Greek form of the Persian *Vishtāspa*). (1) A semi-legendary king (*kava*), praised by Zoroaster as his protector and a true believer, son of Aurvataspa (Lohrasp). The later tradition and the *Shahname* of Firdousi make him (in the modern form Kai Gushtāsp) king of Iran. As Zoroaster probably preached his religion in eastern Iran, Vishtāspa must have been a dynast in Bactria or Sogdiana. The Zoroastrian religion was already dominant in Media in the time of the Assyrian king Sargon (c. 715 B.C.), and had been propagated probably in much earlier times (cf. PERSIA); the time of Zoroaster and Vishtāspa therefore may be put at c. 1000 B.C. (2) A Persian, father of Darius I., under whose reign he was governor of Parthia, as Darius himself mentions in the Behistun inscription (2.65). By Ammianus Marcellinus, xxiii. 6. 32, and by many modern authors he has been identified with the protector of Zoroaster, which is impossible for chronological and historical reasons, and from the evidence of the development of Zoroastrianism itself (see PERSIA: *Ancient History*).

HYSTERESIS. If an unmagnetized iron bar be subjected to a gradually increasing magnetizing force, and the corresponding values of the magnetic induction (flux density) in the iron be determined, then on plotting the magnetizing force against the induction a curve OBC is obtained. If now the magnetizing force is gradually decreased to zero and the values of the magnetic induction determined, it will be found that the curve obtained does not coincide with OBC but takes the form CD. If now the direction of the magnetizing force is reversed, DEF is obtained, and decreasing the magnetizing force again to zero, reversing, and increasing will give the curve FGC. It will be seen from a study of the complete curve that the magnetic induction (flux density) lags behind the magnetizing force. It was to this property of magnetic materials that Ewing gave the name *Hysteresis*. (See MAGNETISM, ELECTROMAGNET, ELECTRIC GENERATOR, ETC.).

HYSTERIA, a term applied to a mental affection which occurs usually in individuals of neurotic and unstable constitu-

tions. It is manifested by an undue susceptibility to external impressions, emotional episodes, and marked sensory, psychic and motor disturbance. Though classed among so-called "nervous" diseases, it is functional in origin, and no organic change in the nervous system is known to exist. Physicians of the past supposed that hysteria occurred only in women and resulted from a wandering of the uterus or womb; hence its name; but after the experiences of the World War it has been more and more clearly realized that men may be as much affected as women.

Though heredity has a definite influence, modern knowledge has shown that environmental factors in early life and faulty education are of main importance.

The modern period in the history of hysteria may be said to have begun with Charcot; since, many physiological and psychological theories have been put forward. The most fruitful work was done by Pierre Janet, who regarded it as a purely mental malady. He believed that the disorder lay in a poor synthesis of the personality so that certain ideas became split off from the main portion of the personality, and in a subconscious region of the mind independently produced these results. Various other theories of such mental dissociation have been formulated and the most important and interpretative is that of Sigmund Freud of Vienna. According to this worker, the hysterical symptom is the result of a conflict between the personality and some "wish" which is out of harmony with the personal ego, and is therefore repressed. (See PSYCHO-ANALYSIS.) The repression, however, is not entirely successful, and the wish in the unconscious mind, being dynamic, forces its way into consciousness in a symbolic and disguised form. The symptom is thus a compromise between the two urges at play. Much of the "wish" material which is repressed Freud believes to be related intimately to the sexual instinct.

The symptoms of hysteria are manifold and complex and may appear in many combinations. They may be physical or mental. Among the former we may note paralysis of limbs, spasms of muscles, tremors, loss of voice or speech, loss of sensation in the skin, blindness, vomiting, etc. The hysterical fit is a convulsive attack which is well known and liable to be confused with epilepsy. There are, however, points of differentiation which careful investigation will usually reveal. The mental symptoms can all be looked upon as the result of the independent functioning of a dissociated part of the content of the mind. The chief are memory gaps, sleepwalking, fugues (wandering attacks of which there is no subsequent recollection), trances, hallucinations, deliria, and dream states. Double personality would be explained on a similar basis. In such a condition the split-off mental functions are so extensive that a second complete personality is formed. Freud classifies hysteria into two forms—conversion hysteria, when the psychic excitation is converted into some bodily innervation, and anxiety hysteria, when the symptoms are purely mental. In the latter category are included those cases evidencing anxiety, depression and morbid fears. In the minor form of hysteria the individual tends to be nervous and excitable, show exaggerated emotion, lack of control, with a liability to phantasy, egoism, and craving for attention and sympathy. Hysteria may be so severe as to constitute insanity. In many of its manifestations its diagnosis is by no means easy and its physical symptoms are not infrequently taken as evidence of bodily disease. Treatment involves the use of some form of psychotherapy. Drug administration is not in the main scientifically admissible. What method of psychotherapy should be applied will vary according to the type of case and other circumstances. Suggestion, hypnotism, and persuasion are of value in properly selected patients. If possible, the psychic cause should be discovered. This may be sought through some form of psychological analysis or through the Freudian technique of psychoanalysis. An education in mental hygiene will generally be indicated.

See McDougall, *Abnormal Psychology*.

(C. S. R.)

HYTHE, a market town and watering-place, one of the Cinque

Ports, and a municipal borough of Kent, England, 67 m. S.E. by E. of London on a branch of the S.R. Pop. (1921) 7,767. It is situated near the eastern extremity of Romney marsh, about half a mile from the sea, and consists principally of one long street running parallel with the shore. On the slope of the hill above the town stands the church of St. Leonard, partly Late Norman, with an Early English chancel. The tower was rebuilt about 1750. In a vault under the ambulatory have been found many skulls and bones transferred from the churchyard from time to time about the 14th and 15th centuries. Lionel Lukin (1742–1834), inventor of the life-boat, is buried in the churchyard. Hythe possesses a guildhall founded in 1794 and two hospitals, that of St. Bartholomew founded by Haimo, bishop of Rochester in 1336, and that of St. John (rebuilt in 1802), still older, founded originally for the reception of lepers.

Lympne, now 3 m. inland, is thought to have been the original harbour which gave Hythe a place among the Cinque Ports. The sea-sand lying on the surface shows the course of the ancient estuary. Here are remains of a Roman fortress, and of the *Portus Lemanis*. Large portions of the fortress walls are standing. At the south-west corner is one of the circular towers which occurred along the line of wall. The site is now occupied by the old castellated mansion of Studfall castle, formerly a residence of the archdeacons of Canterbury. The church at Lympne is Early English, and has a Norman tower built by Archbishop Lanfranc, with some Roman material in the walls. A short distance east is Shipway or Shepway Cross, where some of the great assemblies relating to the Cinque Ports were held. A mile north from Hythe is Saltwood castle, of ancient origin, but rebuilt in the time of Richard II. The castle was granted to the see of Canterbury in 1026, and here the murder of Thomas à Becket is said to have been concerted. It remained a residence of the archbishops until the time of Henry VIII. It was restored as a residence in 1882. About 2 m. N.W. of Saltwood are remains of the fortified 14th century manor-house of Westenhamer, quadrangular and surrounded by a moat, with three of the nine towers (alternately square and round) by which the walls were defended remaining.

Hythe (Heda, Heya, Hethe, Hithel, *i.e.*, landing-place), a port in Saxon times, was granted by a Saxon thegn to Christ Church, Canterbury. In the Domesday Survey the borough is entered among the archbishop's lands as appurtenant to his manor of Saltwood, and the bailiff of the town was appointed by the archbishop. Hythe was evidently a Cinque Port before the Conquest, as King John in 1205 confirmed the liberties which the townsmen had under Edward the Confessor. The liberties of the Cinque Ports were confirmed in Magna Carta and later by Edward I. in a general charter, which was confirmed, often with additions, by subsequent kings down to James II. John's charter to Hythe was confirmed by the Lancastrian kings. These charters were granted to the Cinque Ports in return for the 57 ships which they supplied for the royal service, of which five were contributed by Hythe. The ports were first represented in the parliament of 1365, to which they each sent four members.

Hythe was governed by 12 jurats until 1574, when it was incorporated by Elizabeth under the title of the mayor, jurats and commonalty of Hythe; a fair for the sale of fish, etc., was also granted, to be held on the feast of St. Peter and St. Paul. With the silting up of the harbour Hythe lost its old importance.

HYTHE, CONFERENCE OF, a meeting (May 15 to 17 1920) between the British and French prime ministers, together with the chancellor of the exchequer and the French minister of finance, in preparation for the Conference of Spa (*see* SPA, CONFERENCE OF). A French proposal that France should be granted priority in reparation payments seems to have been put forward but not pressed, and the linking up of the reparation problem with the question of inter-Allied debts was proposed publicly for the first time in the official communiqué.

This letter corresponds to Semitic י (yod) and Greek ι (iota). Early Greek forms from the island of Thera were ζ and Ϻ, which obviously more closely resemble the Semitic than the later single vertical stroke. In Attic inscriptions also the form Ϻ appears, while in early Corinthian inscriptions the forms ζ, Ϻ, Ϻ are found. The Chalcidic alphabet had the form Ι and this was the form in all the Italic alphabets including the Etruscan. The Lydian alphabet besides the form Ι also shows a form Ι (written from right to left).

THE DEVELOPMENT OF THE LETTER "I" FROM THE PHOENICIAN THROUGH THE CLASSICAL LATIN TO THE PRESENT FORM

The minuscule letter is merely a shortened form of the majuscule. The dot first appears in mss. of about the 11th century and was used to distinguish the letter and assist reading in words in which it was in close proximity to letters such as *n* or *m* (*inimicis*, for example). The dot frequently took the form of a dash, e.g., *i*. It became the custom in mediaeval mss. to distinguish an initial or otherwise prominent *i* by continuing it below the line, and it was from this habit that the differentiation of the letters *i* and *j* arose. The initial letter, nearly always lengthened, had most frequently a consonantal force, and this led to *j* representing the consonant, *i* the vowel. The two letters were not considered as separate until the 17th century.

In Semitic the letter represented a spirant akin to the sound of English consonantal *y*. In Greek, Latin and the Romance languages it has represented a high front vowel similar to English long *e*. In Latin short *i* represented a considerably more open sound than long *i*, as is evidenced by the fact that in late Latin it ran together with long *e*. In modern English the sound of short *i* is almost identical with what it was in Latin (e.g., in the word *pit*). Long *i* has become a diphthong (*ai*/*Ti*, e.g., in the words *ice*, *hire*), the sound formerly represented by long *e* (i.e., that heard in French *tête*) having shifted forwards and upwards till it has become that formerly represented by long *i*.

In words such as *fir* the letter represents the neutral vowel, while in certain foreign words it retains its continental sound, identical with that it represented in Middle English and previously (e.g., in the words *pique*, *emir*). (B. F. C. A.)

IACANDONES, an Indian tribe belonging to the Maya-Quiché stock. They occupy the tributary streams west of the Usumacinta river in Chiapas, Mexico. Their tongue is closely related to the Maya of Yucatan. Living in scattered family groups, their total number to-day is only a few hundred. Formerly, however, they were numerous and opposed the Spaniards so resolutely, especially during the 17th century, that they were never completely subdued. Their culture at present is primitive but they show survivals of higher phases inherited from pre-Columbian times.

See A. M. Tozzer, *A Comparative Study of the Mayas and Iacandones* (1907).

IAMBIC, a verse or succession of verses composed wholly or principally of the foot called an iambus (υ-). It is generally described by a compound name consisting of a Greek numeral and the word *metron*, signifying a group of two iambs; as, iambic dimeter, a line consisting of two *metra* or four iambs: "perunxit hoc Iasonem," or "John Gillpin was | a cit|izen." The commonest form, and one of the most popular of Greek metres, especially in drama, is the trimeter (three *metra*, or six iambs). When "pure," i.e., containing no other feet, this runs "suīs et ipsa Rōma viribū ruit." But as a substitute for each of the first five iambs, under various restrictions more or less severe according to subject and language, the ancients allowed a spondee (— —), a tribrach (υ υ υ), a dactyl (— υ υ), an anapaest (υ υ —), sometimes a proceleusmatic (υ υ υ υ). Other common lines are the tetrameter catalectic ("parātus omne Caesaris periculum subire") and acatalectic ("beātus ille qui prōcul negotiis, ut prisca gens"), with similar substitutions allowed. These last two are common in English, as "In good | King Charles's | gol|den days, | when loy|alty | no harm | meant," and "But come, | thou god|dess fair | and free, | in heaven | yclept | Euphro|syne," but the trimeter is almost unknown; Spenser's "Unhappy verse | the witness of | my unhappy state" is an example; the Alexandrine, as "And hope to merit Heaven | by

making earth a hell," has a different rhythm. Its place in our literature is taken by the five-foot line, in couplets or "blank," as "A lit|tle on|ward lend | thy gui|ding hand."

IAMBlichus (d. c. A.D. 330), the chief representative of Syrian Neoplatonism, was born at Chalcis in Coele-Syria of an illustrious family. He studied under Porphyry in Rome, and later taught in Syria. Although his commentaries on Plato and Aristotle, and works on the Chaldaean theology and on the soul, are lost, fragments of them have been preserved by Stobaeus and others. Proclus mentions his five extant books, which are parts of a great work on Pythagorean philosophy, and ascribes to him the celebrated book *On the Egyptian Mysteries*, which probably only emanated from his school. As a philosopher, Iamblichus had little originality. His contemporaries, like his admirers of the 15th and 16th centuries, looked upon him with extravagant veneration, but Eunapius, his biographer, merely says that he was inferior to Porphyry only in style. The modifications of Neoplatonism introduced by Iamblichus were the elaboration of its formal divisions, the more systematic application of the Pythagorean number-symbolism, and chiefly, under the influence of Oriental systems, a mystical colouring. Immediately after the absolute one of Plotinus (see **NEOPLATONISM**), Iamblichus introduced a second superexistent unity as the producer of intellect, and modified the three succeeding moments of the emanation (intellect, soul and nature). He speaks of them as intellectual, supramundane and mundane gods. The first of these is again distinguished into spheres of intelligible gods and of intellectual gods, each subdivided into triads, the latter sphere being the place of ideas, the former of the archetypes of these ideas. He identifies the Demiurge, Zeus, or world-creating potency with the perfected *vous* (intellect), the intellectual triad being increased to a hebdomad, probably (as Zeller supposes) through the subdivision of its first two members. As in Plotinus *vous* produced nature by mediation of *ψυχή* (soul), so here the intelligible gods are followed by a triad of psychic gods. The first of these is incommunicable and supramundane, while the other two seem to be mundane though rational. In the third class, or mundane gods, there is a great variety of gods, angels, demons and heroes. The world is thus peopled by a crowd of superhuman beings influencing natural events, possessing and communicating knowledge of the future, and not inaccessible to prayers and offerings. Nature is bound by the indissoluble chains of necessity, but being the result of higher powers becoming corporeal, a continual stream of elevating influence flows from them, interfering with the necessary laws and turning to good the imperfect and evil which is said to have been generated accidentally.

Iamblichus retains for the soul of men the middle place between intellect and nature which it occupies in the universal order. It descends by a necessary law (not solely for trial or punishment) into the body, and, passing perhaps from one human body to another, returns again to the supersensible by its virtuous activities. To the political, purifying, theoretical and paradigmatic virtues of Porphyry, Iamblichus adds the priestly virtues in which the divinest part of the soul raises itself by insight above intellect to absolute being. His tendency, however, was not so much to raise man to God as to bring the gods down to men. His ethical theory is strongly practical.

The works of Iamblichus are: (1) *On the Pythagorean Life* ed. T. Kiessling (1815), A. Nauck (St. Petersburg, 1884), Eng. trans. by T. Taylor (1818). (2) *The Exhortation to Philosophy*, ed. T. Kiessling (1813); H. Piselli (1888). (3) The treatise *On the General Science of Mathematics*, ed. J. G. Friis (Copenhagen, 1790), N. Festa (Leipzig, 1891). (4) The book *On the Arithmetic of Nicomachus* with fragments on fate and prayer, ed. S. Tennulius (1688), the *Arithmetic* by H. Pistelli (1894). (5) *The Theological Principles of Arithmetic* by F. Ast (Leipzig, 1817). The *Letters to Iamblichus the Philosopher* bearing the name of the emperor Julian are now considered spurious. The *Liber de mysteriis* (ascribed to Iamblichus but most probably by a pupil) was edited with Latin translation and notes, by T. Gale (Oxford, 1678), and by G. Parthey (Berlin, 1857); Eng. trans. by T. Taylor (1821). See G. E. Hebenstreit, *De Iamblichi, philosophi Syri, doctrina* (Leipzig, 1764); Harless, *Das Buch v. d. ägypt. Myst.* (Munich, 1858); T. Whittaker, *The Neo-Platonists* (Cambridge, 2nd ed., 1918); Eunapius, *Vitae Philosophorum*; Zeller, *Phil. d. Griechen*; E. Vacherot, *Hist. de l'école d'Alexandrie* (1846); Überweg, *Grund. der Gesch. der Phil.* Pt. 1. (1926) with full bibliography. See **NEO-PLATONISM**.

IAMBlichus, of Syria, the earliest of the Greek romance writers, flourished in the 2nd century A.D. He was the author of *Βυλωνιακά*, *Ba* the loves of Rhodanes and Sinonis, of which an epitome is preserved in Photius (cod. 94). Only a few fragments have been preserved. According to Suidas Iamblichus is said to have been a freedman.

IAPETUS, in Greek mythology, son of Uranus and Ge, one of the Titans, father of Atlas, Prometheus, Epimetheus, and Menoetius (Hesiod, *Theog.* 507). As a punishment for having revolted against Zeus, he was imprisoned in Tartarus (Homer, *Iliad*, viii. 479) or underneath the island of Inarime off the coast of Campania (Silius Italicus xii. 148). Hyginus makes him the son of Tartarus and Ge, and one of the giants. The etymology of the name is doubtful, but it certainly has nothing to do with the Hebrew Japhet.

See Preller-Robert, i. p. 47.

IAPYDES (i-ahp'-ü-dās) or **IAPODES**, one of the three chief peoples of Roman Illyria. They occupied the interior of the country on the north between the Arsia and Tedanias, which separated them from the Liburnians. Their territory formed part of the modern Croatia. A mixed race of Celts and Illyrians, who used Celtic weapons and tattooed themselves, they were warlike and addicted to plundering expeditions. In 129 B.C. C. Sempronius Tuditanus celebrated a triumph over them, and in 34 B.C. they were finally crushed by Augustus.

See Strabo iv. 207, vii. 313-315; Dio Cassius xlix. 35; Appian, *Illyrica*, 10, 14, 16; Livy, *Epit.* lix. 131; Tibullus iv. 1. 108; Cicero, *Pro Balbo*, 14.

IATROCHEMISTRY (coined from Gr. *ιατρός*, a physician, and "chemistry"), a stage in the history of chemistry, during which the object of this science was held to be "not to make gold but to prepare medicines." This doctrine dominated chemical thought during the 16th century, its foremost supporters being Paracelsus, J. B. van Helmont, and F. de la Boë Sylvius. But it gave way to the new definition formulated by Boyle, viz., that the proper domain of chemistry was "to determine the composition of substances." (See **ALCHEMY**; **CHEMISTRY**.)

IAZYGES (i-ahz'-ü-gās), Sarmatian tribe on the Maeotis, allies of Mithridates the Great (q.v.). Moving westward across Scythia, they were on the lower Danube by the time of Ovid, and about A.D. 50 occupied the plains east of the Theiss. Here, under the general name of Sarmatae, they were a perpetual trouble to Dacia (q.v.) the Roman province. They were divided into free-men and serfs, the latter of whom were probably an older settled population enslaved by nomad masters. They rose against them in A.D. 344, but were repressed. Nothing is heard of Iazyges or Sarmatae after the Hunnish invasions.

IBADAN, a town of British West Africa, in Yorubaland, Southern Nigeria, 123 m. by rail north-east of Lagos, and about 50 m. north-east of Abeokuta. Ibadan is the largest negro city in Africa, having an urban population of over 175,000, and with its farm suburbs, 238,000 inhabitants. It occupies the slope of a hill, and stretches into the valley through which the river Ona flows. It is enclosed by mud walls, which have a circuit of 18 m., and is encompassed by cultivated land 5 or 6 m. in breadth. The native houses are low, thatched structures, enclosing a square court, the only break in the mud wall being the door. There are numerous mosques, *orishas* (idol-houses) and open spaces shaded with trees. There are also buildings in the European style. Most of the inhabitants are engaged in agriculture; but a great variety of handicrafts is also carried on. The administration is in the hands of two chiefs, a civil and a military, the *balí* and the *bal-ogun*. There is also an *iyaloda* or mother of the town, to whom are submitted the disputes of the women. The town is in the province of Oyo and is subject to the authority of the *alafin* (ruler) of Oyo, who is guided by the advice of a British resident. For many years the Ibadans had shown a tendency to flout the authority of the *alafin* and set up a separate rule under their own *balí*. This tendency to the disintegration of Yorubaland was checked, and misrule replaced by good government through reforms instituted by Sir F. D. (Lord) Lugard in 1914-18. (See also **YORUBA**.) (F. R. C.)

IBAGUE, or SAN BONIFACIO DE IBAGUÉ, a city of Colombia and capital of the department of Tolima, about 60m. W. of Bogota and 18m. N.W. of the Nevado de Tolima. Pop. (1900) est. 13,000, (1918) 30,255. Ibague is built on a beautiful plain between the Chipalo and Combeima, small affluents of the Cuello, a western tributary of the Magdalena. Its elevation, 4,300ft. above the sea, gives it a mild, subtropical climate. The plain and the neighbouring valleys produce cacao, tobacco, rice and sugarcane. It is an important commercial centre, being on the road which crosses the Quindio pass, or *paramo*, into the Cauca valley. Ibague was founded in 1550 and was the capital of the republic for a short time in 1854.

IBÁÑEZ, VICENTE BLASCO (1867-1928), Spanish novelist and politician, was born at Valencia. He became an impassioned political agitator and suffered exile, hard labour and frequent imprisonment for his opinions, although he was returned to parliament on eight occasions by his native city. His early novels, such as *Arroz y Tartana*, *La Barraca* and *Cañas y Barro*, deal with life in Valencia and are remarkable for their vivid descriptions. Although a republican, Ibáñez held strong anti-feminist opinions. He travelled extensively and achieved world-wide success as a writer for the cinematograph. Among his best-known novels are *La Catedral* (1903; Eng. trans., *The Shadow of the Cathedral*, 1909); *Sangre y Arena* (1908; Eng. trans., *Blood and Sand*, 1913); *Los cuatro Jinetes del Apocalipsis* (1916; Eng. trans., *The Four Horsemen of the Apocalypse*, 1918) and *Mare Nostrum* (1918; Eng. trans., *Our Sea*, 1920). He was unpopular in Spain, where his writings were ignored by the majority, and he eventually settled in Paris, becoming the centre of a group of politicians with anti-monarchical views. A journey to America led to the production of such novels as *Los Argonautas* and *La Tierra de Todos*, but in these, as in other works, Ibáñez failed to recapture the charm and realism of his regional novels.

IBANS (SEA DAYAKS). Mostly in the south-west of Borneo, but scattered, on account of their migratory habits, over various parts, usually not far from the coast, are the Ibans, who may be described as a butterfly people. The word Iban, or Ivan, meaning "wanderer," was applied to them by the Kayans and has only been adopted by the Ibans themselves within the last half century. Their skin is darker than that of the other tribes and their hair longer; their mouths are often shapeless and their teeth are filed and discoloured by the chewing of betel-nut. They are, however, a most likeable people and are the tribe best known and best liked by Europeans. They are cheerful, talkative, and sociable, but very ready to quarrel and addicted to litigation. Individually they are vain and self-indulgent, and given to boasting and exaggeration. These faults often lead collectively to a want of discipline, their individualistic bent and their camaraderie being responsible for follies, and even excesses, in which every man follows his neighbour. For this reason the chief in an Iban long house or village has less power and influence than is the case among Kayans or Kenyahs. On the other hand, when an Iban is given some special work by a European his vanity impels him to do it well, and, coupled with a natural adaptability, makes him a more loyal adherent of a settled government.

As Ibans rarely remain in one village for more than three years at a stretch, they are not great builders, but in smaller material and in detail they are such skilled artists that their houses, though unsubstantial, are full of conveniences and amenities. Though they are spoken of as sea dyaks, they are not really a sea-faring people; they are often content with makeshift arrangements as to boats, most of their canoes consisting simply of the hollowed out trunks of big trees. In many sorts of decorative work, such as bead or shell-work, and various patterned articles of clothing, they excel. In general, their faults and their virtues alike leap to the eye; but their geniality and willingness, their versatility and humour, make for attractiveness. See BORNEO.

See C. Hose and W. McDougall, *The Pagan Tribes of Borneo* (1912). **IBARRA**, a city of Ecuador and capital of the province of Imbabura, is situated about 50 m. N.N.E. of Quito in lat. 25° N. and long. 78° 10' W., on a small fertile plain at the northern foot of Imbabura volcano, 7,340 ft. above sea-level. Pop. (1926 esti-

mate) 10,000. It stands on the left bank of the Tahuando, a small stream whose waters flow north and west to the Pacific through the Mira, and is separated from the higher plateau of Quito by an elevated transverse ridge of which the Imbabura and Mojanda volcanoes form a part. Ibarra itself has a mild, humid climate, and is set in the midst of orchards and gardens. It is the see of a bishop and has a large number of churches and convents, and many substantial residences. Ibarra has manufactures of cotton and woollen fabrics, hats, sandals (*alpargates*), sacks and rope from *cabulla* fibre, laces, sugar and various kinds of distilled spirits and cordials made from the sugar-cane grown in the vicinity. The city was founded in 1597 by Alvaro de Ibarra, president of Quito. It has suffered from the eruptions of Imbabura, and more severely from earthquakes, that of 1859 causing great damage to its public buildings, and the greater one of Aug. 16, 1868, almost completely destroyed the town and killed a large number of its inhabitants. The village of Carranqui, 14 m. from Ibarra, is the birthplace of Atahualpa, the Inca sovereign executed by Pizarro, and close by is the small lake called Yaguarcocha where the army of Huaynacpac, the father of Atahualpa, inflicted a bloody defeat on the Carranquis. Another aboriginal battle-field is that of Hatuntaqui, near Ibarra, where Huaynacpac won a decisive victory and added the greater part of Ecuador to his realm.

IBERIANS, an ancient people inhabiting parts of the Spanish peninsula. The name was applied by the earlier Greek navigators to the peoples who inhabited the eastern coast of Spain; originally those who dwelt by the river Iberus (mod. *Ebro*). The river's name itself may represent the Basque phrase *ibay-erri*, "the country of the river." In older Greek usage the term Iberia embraced the country as far east as the Rhone and by the time of Strabo it was the common Greek name for the Spanish peninsula. Iberians thus meant sometimes the population of the peninsula in general and sometimes one element in that population. In Spain, when this element first became known to the Greeks and Romans, there existed many separate and variously civilized tribes connected by at least apparent identity of race, and by similarity (but not identity) of language, and sufficiently distinguished by their general characteristics from Phoenicians, Romans and Celts.

1. **Numismatic.**—Knowledge of ancient Iberian language and history is mainly derived from a variety of coins, found widely distributed in the peninsula, and also in the neighbourhood of Narbonne. (For the prehistoric civilization of the peninsula as a whole see SPAIN.) They are inscribed in an alphabet which has many points of similarity with the western Greek alphabets, and some with the Punic alphabet, but retains a few characters from an older script. The same Iberian alphabet is found also rarely in inscriptions. The coinage began before the Roman conquest was completed; the monetary system resembles that of the Roman republic, with values analogous to *denarii* and *quinarii*. The coin inscriptions usually give only the name of the town; e.g., *Plpilis* (Bilbilis), *Klagriqs* (Calagurris), *Segbrics* (Segobriga), *Tmanuav* (Dumania). The types show late Greek and perhaps also late Punic influence, but approximate later to Roman models. The commonest reverse type, a charging horseman, reappears on the Roman coins of Bilbilis, Osca, Segobriga and other places. Another common type is one man leading two horses or brandishing a sword or a bow. The obverse has usually a male head, sometimes inscribed with what appears to be a native name.

2. **Linguistic.**—The survival of the Basque language (*q.v.*) around the west Pyrenees suggested the attempt to interpret by its means a large class of similar-sounding place names of ancient Spain, some of which are authenticated by their occurrence on the inscribed coins, and to link it with other traces of non-Aryan speech round the shores of the western Mediterranean and on the Atlantic seaboard of Europe. K. W. von Humboldt contended that there existed once a single great Iberian people, speaking a distinct language of their own; that an essentially "Iberian" population was to be found in Sicily, Sardinia and Corsica, in southern France, and even in the British Isles; and that the Basques of the present day were remnants of this race, which had elsewhere been expelled or absorbed. He adduced explanations

of a vast number of the ancient topographical names of Spain, and of other asserted Iberian districts, by the forms and significations of Basque.

3. **Anthropological**—This "Iberian theory" depended partly on the widespread similarity of physical type among the population of south-western Europe. Anthropological researches have proved the existence in Europe, from Neolithic times, of a race, small of stature, with long or oval skulls, who buried their dead in tombs. Their remains have been found in Belgium and France, in Britain, Germany and Denmark, as well as in Spain; and they bear a close resemblance to a type common among the Basques and all over the Iberian peninsula. This Neolithic race has consequently been nicknamed "Iberians," and the racial characteristics of "Iberians," have been identified in the "small swarthy Welshman," the "small dark Highlander," and the "Black Celts to the west of the Shannon," as well as in the typical inhabitants of Aquitania and Brittany. Thus a race with fairly uniform characteristics was at one time in possession of the south of France (or at least of Aquitania), the whole of Spain from the Pyrenees to the straits, the Canary Islands (the Guanches) a part of northern Africa and Corsica. Whether this type is more conveniently designated by the word *Iberian*, or by some other name ("Eur-African," "Mediterranean," etc.) is a matter of comparative indifference, provided that there is no misunderstanding as to the steps by which the term *Iberian* attained its meaning in modern anthropology.

IBERVILLE, PIERRE LE MOYNE, SIEUR D' (1661–1706), French-Canadian soldier and colonizer of Louisiana, was born in Montreal, Canada, on July 16, 1661. He was one of eleven sons of Charles Le Moyne, all of whom performed distinguished service in the extension of the French empire in America. The elder son, Charles Le Moyne, Baron de Longueuil, later became governor of Canada. A younger son, Jean Baptiste Sieur d'Bienville, became Iberville's lieutenant in founding the Louisiana colony, and later first governor of that province. At the age of 14 d'Iberville was appointed midshipman in the French navy and sent to France. After four years service on French ships he returned to Canada. In 1686 he led a detachment on the overland expedition under De Troyes against the English forts on Hudson bay and aided in the reduction of forts Monsipi, Rupert and Kitchichouame (later Fort Albany), also with the aid of his brothers capturing two English vessels. He was left in command of the forts, 1686–89, and in 1688 succeeded in taking two more English ships. In 1690 he was a leader of the French expedition against Schenectady, but before the end of the year returned to Hudson bay to recapture Fort Albany which had relapsed into English control. In 1694 he led a land expedition which captured Ft. Nelson, on Hudson bay. During the winter of 1696–97 he captured Fort Pemaquid and ravaged the English settlements on the coast of Newfoundland. In 1697, in command of a frigate, he again entered Hudson bay and defeated three superior English vessels in a desperate engagement. Afterwards he again took Fort Nelson which the English had recaptured. After the Peace of Ryswick d'Iberville was called to France and commissioned by the marine minister, Pontchartrain, to found a settlement at the mouth of the Mississippi. He left Brest in Oct. 1698 with four vessels and 200 colonists and reached Mobile bay in Jan. 1699. Here the colonists were left while d'Iberville and a number of men searched the coast for the Mississippi, which was entered at the delta and ascended probably to the mouth of the Red river. No favourable site for a colony was found along the river, and, it being late, d'Iberville built Ft. Maurepas on the present site of Biloxi, Miss., and there left his colonists. This was the first permanent French settlement on the Gulf coast.

Returning the next year, d'Iberville built a post on the Mississippi river near New Orleans and explored much of the lower valleys of the Red and Mississippi rivers. Returning a third time in 1701, he found his colony badly reduced by disease and transferred most of the colonists to Mobile. He returned for additional colonists, but France was again at war, and d'Iberville was retained for naval service. He was given command of the West Indian fleet, and in 1706 invaded the islands of Nevis and St.

Christopher forcing them to surrender and capturing 30 ships and 1750 men. While outfitting at Havana for an expedition against the Carolinas, he fell ill with fever and died July 9, 1706.

D'Iberville's journal is found in B. F. French, *Historical Collections of Louisiana and Florida*, 2nd series (1875). See also H. Gravier, *L'Oeuvre de d'Iberville à la Louisiane* (1899); C. B. Reed, *The First Great Canadian* (1910).

IBEX, the Alpine wild goat, *Capra ibex*. Formerly common in the Alps, the ibex is now confined to the Gran Paradiso range in

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE IBEX OR ALPINE WILD GOAT

the neighbourhood of Cogne, and to the Swiss National Park in the Engadine. It measures about 4½ ft. in length and stands about 40in. at the shoulder. In summer the short fur is ashy grey, but in winter this is concealed by long yellowish-brown hairs. The horns are long, curved backwards and ridged on the front surface. The forelegs are somewhat shorter than the hind-limbs. The agility of the ibex on its native mountains is astounding. It inhabits the line of perpetual snow, descending at night to graze in the highest woods. The ibex is gregarious, living in small herds, but the old males are usually solitary. The female, after a period of gestation of 90 days, produces a single young one, which is at once able to follow her. The flesh resembles mutton, but with a flavour of game.

The name "ibex" has been extended to include allied species of which the Asiatic ibex (*C. sibirica*), ranging over Central Asia, is the finest and may possess horns 60in. long. Other species, differing in the thickness of and ridges on the horns, occur in Arabia, Abyssinia, the Caucasus and the Pyrenees, and the name is also applied to the short-horned Indian *Hemitragus hylocrius* from the Nilgiris.

IBIS, one of the sacred birds of ancient Egypt, *Ibis aethiopica*. The myth of the Ibis is explained by Renouf in his *Hibbert Lectures*. The ibis inhabits the Nile basin from Dongola southward, as well as Kordofan and Sennar. It arrives in Egypt in summer, disappearing again as the Nile subsides. It is somewhat larger than a curlew, with a much stouter beak and legs. The plumage is black and white, the bare head and neck being black. The bill and feet are black. The birds nest in colonies in trees or bushes; two to four white eggs spotted with reddish-brown are laid. The young are hatched in August.

THE WHITE-FACED GLOSSY IBIS

the counterpart of the Christian and Jewish devil. He figures oftener in the Qur'an under the name Shaytān, Iblis being mentioned 11 times, whereas Shaytān appears in 87 passages. Iblis rebelled against Allāh and was expelled from Paradise but was afterwards respited till the Judgment day (Qur'an vii. 13). The Qur'anic story is that his fall was a punishment for his refusal to worship Adam.

See *Iblīs* (in *Encyclopaedia of Islam*, bibl.); L. Massignon, *Al-Hallaḡ*, p. 869 sqq. (1922).

IBLĪS, in Muslim mythology

IBN 'ABD RABBIHI (Abū 'Umar Aḥmad ibn Mohammed ibn 'Abd Rabbihi) (860–940), Arabian poet, was born in Cordova. He enjoyed a great reputation for learning and eloquence. No diwan of his is extant, but many selections from his poems are given in the *Yatimat ud-Dahr*, i. 412–436 (Damascus, 1887). His great anthology, the *Iqd ul-Farid* ("The Precious Necklace"), is an *adab* book (see ARABIA: Literature, section "Belles Lettres") resembling Ibn Qutaiba's *Uyūn ul-Akhbār*, from which it borrows largely. It has been printed several times in Cairo (1876, 1886).

IBN 'ARABĪ [Muḥyiddīn Abū 'Abdallāh ibn ul-'Arabī] (1165–1240), Muslim theologian and mystic, was born in Murcia and educated in Seville. When thirty-eight he travelled in Egypt, Arabia, Baghdad, Mosul and Asia Minor, after which he lived in Damascus for the rest of his life. In law he was a Zahirite, in theology a mystic of the extreme order, though professing orthodox Ash'arite theology and combating in many points the Indo-Persian mysticism (pantheism). He claims to have had conversations with all the prophets past and future, and reports conversations with God himself. Of his numerous works about 150 still exist. The most extensive is the twelve-volume *Futūḥāt ul-Makkiyāt* ("Meccan Revelations"), a general encyclopaedia of Sufic beliefs and doctrines.

Of some 289 works said to have been written by Ibn 'Arabī 150 are mentioned in C. Brockelmann's *Gesch. der arabischen Literatur*, vol. i. (Weimar, 1898), pp. 441–448. See also R. A. Nicholson, *A Literary History of the Arabs*, pp. 399–404 (1907).

IBN ATHĪR, the family name of three brothers, all famous in Arabian literature, born at Jazīrat ibn 'Umar in Kurdistan. The eldest brother, MAJD UD-DĪN (1149–1210), was long in the service of the amir of Mosul. His dictionary of traditions (*Kitāb un-Nihāya*) was published at Cairo (1893), and his dictionary of family names (*Kitāb ul-Murassa'*) has been edited by Seybold (Weimar, 1896). The youngest brother, DİYĀ UD-DĪN (1163–1239), served Saladin from 1191 on, then his son, al-Malik ul-Afdal, and was afterwards in Egypt, Samosata, Aleppo, Mosul and Baghdad. He was one of the most famous aesthetic and stylistic critics in Arabian literature. His *Kitāb ul-Mathal*, published in Bulāq in 1865 (cf. *Journal of the German Oriental Society*, xxxv., and Goldziher's *Abhandlungen*, i.), contains some very independent criticism. Some of his letters have been published by D. S. Margoliouth "On the Royal Correspondence of Diya ed-Din el-Jazari" in the *Actes du dixième congrès international des orientalistes*, sect. 3.

The brother best known by the simple name of Ibn Athīr was ABU-L-ḤASAN 'IZZUDDĪN MAHOMMED IBN UL-ATHĪR (1160–1234), who devoted himself to history. At the age of twenty-one he settled in Mosul. In the service of the amir for many years, he visited Baghdad and Jerusalem and later Aleppo and Damascus. His great history, the *Kāmil*, which extends to 1231, was edited by C. J. Tornberg, *Ibn al-Athīri Chronicon quod perfectissimum inscribitur* (14 vols., Leiden, 1851–76), and has been published in 12 vols. in Cairo (1873 and 1886). The first part of this work up to A.H. 310 (A.D. 923) is an abbreviation of the work of Ṭabarī (q.v.) with additions. Ibn Athīr also wrote a history of the Atabegs of Mosul, published in the *Recueil des historiens des croisades* (vol. ii., Paris); a work (*Usd ul-Ghāba*), giving an account of 7,500 companions of Mohammed (5 vols., Cairo, 1863), and a compendium (the *Lubāb*) of Sam'āni's *Kitāb ul-Anṣab*. (Cf. F. Wüstenfeld's *Specimen el-Lobabi*, Göttingen, 1835.)

IBN BATUTA, i.e., Abu Abdullah Mohammed, surnamed Ibn Batuta (1304–1378), the greatest of Moslem travellers, was born at Tangier in 1304. He entered on his travels in 1325 and closed them in 1355. He began by traversing the Mediterranean coast from Tangier to Alexandria, marrying twice on the road. After some stay at Cairo, and an unsuccessful attempt to reach Mecca from Aidhab on the west coast of the Red Sea, he visited Palestine, Aleppo and Damascus. He then made the pilgrimage to Mecca and Medina, and visited the shrine of Ali at Nejef (Mashhad-Ali), travelling to Basra, and across the mountains of Khuzistan to Isfahan, thence to Shiraz and back to Kufa and Baghdad. After an excursion to Mosul and Diarbekr, he made the *haj* a second time, staying at Mecca three years. He next sailed

down the Red Sea to Aden (then a place of great trade), the singular position of which he describes, noticing its dependence for water-supply upon the great cisterns restored in modern times. He continued his voyage down the African coast, visiting, among other places, Mombasa and Quiloa (Kilwa). Returning north he passed by the chief cities of Oman to New Ormuz (Hurmuz), which about 1315 had been transferred to its famous island-site from the mainland (Old Ormuz). After visiting other parts of the gulf he crossed Arabia to Mecca, making the *haj* for the third time. Crossing the Red Sea, he made a journey to Aswan (Syene) and along the Nile to Cairo. After this, travelling through Syria, he made a circuit among the petty Turkish states. He now crossed the Black Sea to Kaffa, then mainly occupied by the Genoese, and apparently the first Christian city he had seen, for he was much perturbed by the bell-ringing. He next travelled into Kipchak (the Mongol khanate of Russia), and joined the camp of the reigning khan Mohammed Uzbek, from whom the *Uzbek* race is perhaps named. Among other places in this empire he travelled to Bolghar (54° 54' N.) in order to witness the shortness of the summer night, and desired to continue his travels north into the "Land of Darkness" (in the extreme north of Russia), but was obliged to forego this.

Returning to the khan's camp he joined the cortège of one of the Khatuns, who was a Greek princess and in her train travelled to Constantinople, where he had an interview with the emperor Andronikos III. the Younger (1328–1341). He tells how, as he passed the city gates, he heard the guards muttering *Sarakinu*. Returning to the court of Uzbek, at Sarai on the Volga, he crossed the steppes to Khwarizm and Bokhara; thence through Khorasan and Kabul, and over the Hindu Kush (to which he gives that name, its first occurrence). He reached the Indus in 1333.

Sojourn in the East.—From Sind, which he traversed to the sea and back again, he went to Multan, and eventually, on the invitation of Mahommed Tughlak, the reigning sovereign, to Delhi. He appointed the traveller to be kazi of Delhi. In the sultan's service Ibn Batuta remained eight years; but his good fortune stimulated his natural extravagance, and his debts soon amounted to four or five times his salary. He fell into disfavour and retired from court, only to be summoned again to accompany an embassy to the emperor of China, last of the Mongol dynasty. The party travelled through central India to Cambay and thence sailed to Calicut, classed by the traveller with the neighbouring Kaulam (Quilon), Alexandria, Sudak in the Crimea, and Zayton (Amoy harbour) in China, as one of the greatest trading havens in the world. The party was to embark in Chinese junks (the word used) and smaller vessels, but that carrying the other envoys and the presents, which started before Ibn Batuta was ready, was totally wrecked; the vessel that he had engaged went off with his property, and he was left at Calicut. Not daring to return to Delhi, he remained about Honore and other cities of the western coast, taking part in various adventures, among others the capture of Sindabur (Goa), and visiting the Maldivé islands, where he became kazi, and married four wives. In 1344 he left the Maldives for Ceylon; here he made the pilgrimage to the "Footmark of our Father Adam." Thence he went to Malabar (the Coromandel coast), where he joined a Mussulman adventurer of Madura. After again visiting Malabar, Canara and the Maldives, he left for Bengal, a voyage of 43 days, landing at Sadkawan (Chittagong). In Bengal he visited the Moslem saint Shaykh Jalaluddin, whose shrine (Shah Jalal at Silhet) is still maintained. Returning to the delta, he took a junk at Sunarganw (near Dacca) bound for Java (i.e., Java Minor of Marco Polo, or Sumatra). He reached Sumatra in 40 days, and was provided with a junk for China by Malik al Dhahir, disciple of Islam. Calling (apparently) at Cambodia on his way, Ibn Batuta reached China at Zayton (Amoy harbour), famous from Marco Polo; he also visited Sin Kalan or Canton, and professes to have been in Khansa (Kinsay of Marco Polo, i.e., Hangchau), and Khanbalik (Cambaluc or Peking).

The Return Journey.—On his way home he saw the great bird *Rukh* (evidently, from his description, an island lifted by refraction); revisited Sumatra, Malabar, Oman, Persia, Baghdad,

and crossed the great desert to Palmyra and Damascus, where he got his first news of home, and heard of his father's death 15 years before. Diverging to Hamāth and Aleppo, on his return to Damascus, he found the Black Death raging. Revisiting Jerusalem and Cairo he made the *haj* a fourth time, and finally reappeared at Fez (visiting Sardinia *en route*) on Nov. 8, 1349, after 24 years' absence. Morocco, he felt, was, after all, the best of countries. "The *dirhems* of the West are but little; but then you get more for them." After going home to Tangier, Ibn Batuta crossed into Spain and toured Andalusia, including Gibraltar, following a siege from the "Roman tyrant Adfunus" (Alphonso XI. of Castile, 1312-1350). In 1352 he started for Central Africa, passing by the oases of the Sahara (where the houses were built of rock-salt, as Herodotus tells, and roofed with camel skins), to Timbuktu and Gogo on the Niger, a river which he called the Nile, believing it to flow down into Egypt. Being then recalled by his own king, he returned to Fez (early in 1354) via Takadda, Haggar and Tuat. Thus ended his 28 years' wanderings which easily exceeded 75,000 miles. By royal order he dictated his narrative to Mohammed Ibn Juzai, who concluded the work (1355), with the declaration: "This Shaykh is the traveller of our age; and he who should call him the traveller of the whole body of Islam would not exceed the truth." Ibn Batuta died in 1378, aged 73.

Ibn Batuta's travels have only been known in Europe during the 19th century; at first merely by Arabic abridgments in the Gotha and Cambridge libraries. Notices or extracts had been published by Seetzen (c. 1808), Kosegarten (1818), Apetz (1819) and Burckhardt (1819), when in 1829 Dr. S. Lee published for the Oriental Translation Fund a version from the abridged mss. at Cambridge, which attracted interest. The French capture of Constantina (Spain, 40 m. N. of Seville) afforded mss. of the complete work, one of them the autograph of Ibn Juzai. And from these, after versions of fragments by various French scholars, was derived at last (1858-59) the standard edition and translation of the whole by M. Défrémery and Dr. Sanguinetti, in 4 vols. See also Sir Henry Yule, *Cathay*, ii. 397-526; C. Raymond Beazley, *Dawn of Modern Geography*, iii. 535-538; and a volume of *Selections* (Broadway Travellers series, 1927).

IBN DURAID (Abū Bakr Mohammed ibn ul-Hasan ibn Duraid ul-Azdī) (837-934), Arabian poet and philologist, was born at Basra of south Arabian stock, but fled in 871 to Oman at the time Basra was attacked by the negroes, known as the Zanj, under Muḥallabī. In 883 he went to Persia, where he remained until 920 when he settled in Baghdad.

The poem *Maqṣūra* was edited by A. Haitsma (1773), E. Scheidius (1786) and N. Boyesen (1828). The *Kitāb ul-Ishtiqāq* ("Book of Etymology"), ed. F. Wüstenfeld (Göttingen, 1854), was written in opposition to the anti-Arabian party to show the etymological connection of the Arabian tribal names. The *Jamhara fi-l-Luḡha*, a large dictionary in Persian, is not printed. See Brockelmann, *Gesch. der arab. Lit.* i. (Weimar, 1898).

IBN EZRA, ABRAHAM BEN MEIR: see ABENEZRA.

IBN FARADĪ (Abū-l-Walid 'Abdallāh ibn ul-Faradī) (962-1012), Arabian historian, was born at Cordova and studied law and tradition. In 992 he made the pilgrimage and proceeded to Egypt and Kairawān. After his return in 1009 he became *cadi* in Valencia, and was killed at Cordova when the Berbers took the city.

His chief work is the *History of the Learned Men of Andalusia*, edited by F. Codera (Madrid, 1891-92). He wrote also a history of the poets of Andalusia. (G. W. T.)

IBN FĀRID (Abū-l-Qāsim 'Umar ibn ul-Fārid) (1181-1235), Arabian poet, was born in Cairo, lived for some time in Mecca and died in Cairo. His poetry is entirely Sufic, and he was esteemed the greatest mystic poet of the Arabs. His *diwan* was published with commentary at Beirut, 1887, etc.; with the commentaries of Burīnī (d. 1615) and 'Abdul-Ghānī (d. 1730) at Marseilles, 1853, and at Cairo; and with the commentary of Rushayyid Ghālīb (19th century) at Cairo, 1893. One of the separate poems was edited by J. von Hammer Purgstall as *Das arabische hohe Lied der Liebe* (Vienna, 1854).

See R. A. Nicholson, *A Literary History of the Arabs* (1907).

(G. W. T.)

IBN GABIROL (SOLOMON BEN JUDAH, or AVICEBRON and AVENCEBROL to the Schoolmen) (c. 1021-c. 1058-1070), Jewish

poet and philosopher, was born at Malaga. His early years were spent at Saragossa, where he came under the protection of Samuel ha-Nagid, the well known patron of learning. At the age of 16 he is supposed to have written poems including the *'Anaq*, a poem on grammar, partially extant. He first popularized the use of Arabic metres in Hebrew, and it is as a poet that he has been remembered by the Jews. To the liturgy he contributed many fine lyrical compositions, the best known being the philosophical *Kether Malkūth* (for the Day of Atonement) and the *Azharōth*, on the 613 precepts (for *Shebhu'ōth*).

Ibn Gabirol's chief philosophical work, which was translated from Arabic into Latin by Johannes Hispalensis and Gundisalvi under the title, *Fons Vitae*, exercised a wide influence on the Schoolmen, though Jewish thinkers practically ignored it because of its non-religious attitude and its neo-Platonic inspiration. In it, Ibn Gabirol speaks of God as unknowable and transcendental, but he tries to save Him from being impersonal by making His wisdom the ground of all being and by admitting the activity of His will in the production of the universe. His views on the Will are peculiar, for he regards it as an hypostasis identifiable in itself with the Divine nature, but distinguishable inasmuch as it is active. Elsewhere he says it is to the world as soul to body, holding it together and penetrating it as a principle of movement. From the Will emanate the intelligences which, as creatures, must possess two factors, namely, universal matter and universal form. The former, which is the source of the potentiality and finite nature in spiritual beings, sustains the universal form which confers the perfecting properties. The intelligences produce the corporeal world in which universal matter is differentiated into *materia universalis corporalis*, *materia universalis caelestis*, *materia universalis naturalis* and *materia particularis naturalis*. To these types of matter there are corresponding forms.

BIBLIOGRAPHY.—Besides the above mentioned works, Ibn Gabirol wrote *Islāh al-akhlāq*, a popular ethical work (Arabic text and Eng. trans. by S. S. Wise, New York, 1901) and a collection of moral maxims (Eng. trans. New York, 1925, Hebrew and English edit. by Ascher, 1859); Texts of the liturgical poems are to be found in the prayer-books; others in Dukes and Edelmann, *Treasures of Oxford* (Oxford, 1850); Dukes, *Shīr Shelomoh* (Hanover, 1858); S. Sachs, *Shīr ha-shīrīm asher li-Shelomoh* (Paris, 1868, incomplete); Brody; *Die weltlichen Gedichte des . . . Gabirol* (Berlin, 1897, etc.). The Latin text of the *Fons Vitae* was published by C. Baumeister (Münster, 1892). See S. Munk, *Mélanges de Philos. juive et arabe* (1859); Wittmann, *Die Stellung des hl. T. von Aquin zu Avencebrol* (Münster, 1900) and *Zur Stellung Avencebrol's im Entwicklungsgang der arabischen Philosophie* (Münster, 1905); D. Neumark, *Gesch. d. jud. Philos. im Mittelalt.* i. (1907) and I. Husik, *Hist. of Mediaeval Jewish Philosophy* (1916); J. Guttman, *Die Philosophie des Ibn Gabirol* (Göttingen, 1889); D. Kaufmann, *Studien über Sal. ibn Gabirol* (Budapest, 1899).

IBN HAUḲAL, strictly Ibn Hauqal, a 10th century Arabian geographer. Nothing is known of his life. His work on geography, written in 977, is only a revision and extension of the *Masālik ul-Mamālik* of al-Iṣṭakhri who wrote in 951. This itself was a revised edition of the *Kitāb ul-Ashkāl* or *Ṣuwar ul-Aqālīm* of Abū Zaid ul-Balkhī, who wrote about 921. Ibn Hauḳal's work was published by M. J. de Goeje (Leiden, 1873). An anonymous epitome of the book was written in 1233.

See M. J. de Goeje, "Die Iṣṭakhri-Balkhī Frage," in the *Zeitschrift der deutschen Morgenländischen Gesellschaft*, xxv. 42 sqq.

IBN ḤAZM (Abū Mohammed 'Alī ibn Ahmad ibn Ḥazm) (994-1064), Moslem theologian, was born in a suburb of Cordova. He studied history, law and theology, and became a vizier as his father had been before him, but was deposed for heresy, and spent the rest of his life quietly in the country. In legal matters he belonged first to the Shāfi'ite school, but came to adopt the views of the Zāhirites, who admitted only the external sense of the Koran and tradition, disallowing the use of analogy (*Qiyās*) and *Taqlīd* (appeal to the authority of an imām), and objecting altogether to the use of individual opinion (*Ra'y*). Ibn Ḥazm extended the application of these principles from the study of law to that of dogmatic theology. His chief work is the *Kitāb ul-Mīlāl wan-Nihāl*, or "Book of Sects" (published in Cairo, 1899).

For his teaching cf. I. Goldziher, *Die Zahiriten*, pp. 116-174 (Leipzig,

1884), and M. Schreiner in the *Journal of the German Oriental Society*, lii. 464-486. For a list of his other works see C. Brockelmann's *Geschichte der arabischen Literatur*, vol. i. (Weimar, 1898), p. 400.

IBN HISHĀM (Abū Mohammed 'Abdulmalik ibn Hishām ibn Ayyūb ul-Himyārī) (d. 834), Arabian biographer, studied in Kufa but lived afterwards in Fostāt (old Cairo), where he gained a name as a grammarian and student of language and history. His chief work is his edition of Ibn Ishāq's (q.v.) *Life of the Apostle of God*, ed. by F. Wüstenfeld (Göttingen, 1858-1860).

IBN ISHĀQ (Mohammed ibn Ishāq Abū 'Abdallāh) (d. 768), Arabic historian, lived in Medina, where he interested himself to such an extent in the details of the Prophet's life that he was accused of rationalism. He consequently left Medina in 733, and went to Alexandria, then to Kufa and Hira, and finally to Baghdad, where he wrote the *Life of the Apostle of God*, which is now lost and is known to us only in the recension of Ibn Hishām (q.v.). The work has been attacked by Arabian writers (as in the *Fihrist*) as untrustworthy, and it seems clear that he introduced forged verses (cf. *Journal of the German Oriental Society*, xiv.). It remains, however, one of the most important works of the age.

IBN JUBAIR [Abū-l Ḥusain Maḥmmed ibn Aḥmad ibn Jubair] (1145-1217), Arabian geographer, was born in Valencia. At Granada he studied the Koran, tradition, law and literature, and later became secretary to the Mohad governor of that city. During this time he composed many poems. In 1183 he left the court and travelled to Alexandria, Jerusalem, Medina, Mecca, Damascus, Mosul and Baghdad, returning in 1185 by way of Sicily.

The *Travels of Ibn Jubair* were edited by W. Wright (Leiden, 1852); and a new edition of this text, revised by M. J. de Goeje, was published by the Gibb Trustees (London, 1907). The part relating to Sicily was published, with French translation and notes, by M. Amari in the *Journal asiatique* (1845-46) and a French translation alone of the same part by G. Crolla in *Museon*, vi. 123-132.

IBN KHALDŪN (Abū Zaid ibn Mohammed ibn Mohammed ibn Khaldūn) (1332-1406), Arabic historian, was born at Tunis. In 1352 he entered the service of the Marinid sultan Abū Inān (Faris I.) at Fez, but in 1356, his integrity having been suspected, he was imprisoned for two years. Later, having offended the prime minister, he emigrated to Granada, where he was received with great cordiality by Ibn al Ahmar. This excited the jealousy of the vizier, and he was driven back to Africa (1364), where he entered the service of the sultan of Tlemçen. A few years later he was taken prisoner by Abdalaziz ('Abd ul 'Aziz'), who had seized the throne. He then entered a monastic establishment, until 1370 when the new sultan recalled him to Tlemçen. In 1378 he entered the service of the sultan of his native town of Tunis, where he devoted himself to his studies and wrote his history of the Berbers. While on a pilgrimage to Mecca, he visited Cairo, where he was presented to the sultan, al-Malik udh-Dhahir Barkuk, who insisted on his remaining there, and in 1384 made him grand cadi of the Malikite rite for Cairo. Later he made the pilgrimage to Mecca, and on his return lived in retirement in the Fayum until 1399, when he was called to resume his functions as cadi. He was removed and reinstated in the office no fewer than five times.

In 1400 he was sent to Damascus, in connection with the expedition intended to oppose Timur or Tamerlane. When Timur had become master of the situation he permitted Ibn Khaldūn to return to Egypt. Ibn Khaldūn died on March 16, 1406.

His chief work, the "Universal History," deals more particularly with the history of the Arabs of Spain and Africa, and includes a short autobiography. An edition of the Arabic text was printed at Būlāq (7 vols., 1867) and a part of the work has been translated by de Slane under the title of *Histoire des Berbères* (Algiers, 1852-56). Vol. i., the *Muqaddama* (preface), was published by M. Quatremère (3 vols., Paris, 1858), often republished in the East, French translation by de Slane (3 vols., Paris, 1862-68). The parts of the history referring to the expeditions of the Franks into Moslem lands were edited by C. J. Tornberg (Upsala, 1840), and the parts treating of the Banu-l Ahmar kings of Granada were translated into French by M. Gauderoy-Demombynes in the *Journal asiatique*, ser. 9, vol. xiii. The *Autobiography* was translated into French by de Slane in the *Journal asiatique*, ser. 4, vol. iii. See R. Flint, *History of the Philosophy of History* (Edinburgh, 1893).

IBN KHALLIKĀN [Abū-l 'Abbās Aḥmad ibn Khallikān] (1211-1282), Arabian biographer, was born at Arbela. When eighteen he went to Aleppo, where he studied for six years, then to Damascus, and in 1238 to Alexandria and Cairo. In 1261 he became chief cadi of Syria in Damascus, from 1271 to 1278, he was professor in Cairo, and from 1281 to his death, professor in Damascus.

His great work, the *Kitab Wafayāt ul-A'yān*, contains in alphabetical order the lives of the most celebrated persons of Muslim history and literature, except those of Mahomet, the four caliphs and the companions of Mahomet and their followers (the *Tābiūn*). It was published by F. Wüstenfeld (Göttingen, 1835-43), in part by McG. de Slane (Paris, 1838-42), and also in Cairo (1859 and 1882). An English translation by McG. de Slane was published in 4 vols. (London, 1842-71). Thirteen extra biographies from an Amsterdam ms. were published by Pijnappel (Amsterdam, 1845). The best known supplement to the book is that of Maḥmmed ibn Shākir (d. 1362), published in Cairo 1882. A collection of poems by Ibn Khallikān is also extant. See E. V. Lucas, *A Boswell of Baghdad* (I.K.) (1917).

IBN QUTAIBA or **KOTAIBA** [Abū Mohammed ibn Muslim ibn Qutaiba] (828-889), Arabian writer, was born at Baghdad or Kufa, and was of Iranian descent. He became cadi in Dinawār and afterwards teacher in Baghdad, where he died. He was the first representative of the eclectic school of Baghdad philologists that succeeded the schools of Kufa and Baṣra. (See ARABIA: Literature, section "Grammar.") Although engaged also in theological polemic (cf. I. Goldziher, *Muhammedanische Studien*, ii. 136, Halle, 1890), his chief works were directed to the training of the ideal secretary. Of these five form a series. The *Adab ul-Kātib* ("Training of the Secretary") contains instruction in writing and is a compendium of Arabic style. It has been edited by Max Grünert (Leyden, 1900). The *Kitāb ush-Sharāb* is still in ms. The *Kitāb ul-Ma'ārif* has been edited by F. Wüstenfeld as the *Handbuch der Geschichte* (Göttingen, 1850, summary in E. G. Browne, *A Literary History of Persia*, 1902); the *Kitāb ush-Shi'r wash-Shu'arāi* ("Book of Poetry and Poets") edited by M. J. de Goeje (Leyden, 1904). The fifth and most important is the *Uyūn ul-Akhbār*, which deals with lordship, war, nobility, character, science and eloquence, asceticism, friendship, requests, foods and women, with many illustrations from history, poetry and proverb (ed. C. Brockelmann, Leyden, 1900 sqq.).

For other works see C. Brockelmann, *Gesch. der arabischen Literatur*, vol. i. (Weimar, 1898).

IBN SA'D [Abū 'Abdallāh Mohammed ibn Sa'd ibn Manī' uz-Zuhri, often called Kātib ul-Waqidi ("secretary of Waqidi") of Baṣra] (d. 845), Arabian biographer, lived chiefly in Baghdad. His *Kitāb ul-Tabaqāt ul-Kabīr* (15 vols.) contains the lives of Mahomet, his Companions and Helpers and of the following generation.

It has been edited under the superintendence of E. Sachau (Leiden, 1904 sqq.); cf. O. Loth, *Das Classenbuch des Ibn Sa'd* (Leipzig, 1869).

IBN SA'UD or **'ABDUL 'AZIZ IBN 'ABDULRAHMAN IBN FAISAL IBN SA'UD**, was born at Riyadh, capital of Nejd, about 1880. His father, 'AbdulRahman (d. 1928), was the youngest of the four sons of the Amir Faisal, Sultan of Nejd from 1834 to 1867. The latter's death had plunged Central Arabia into a state of anarchy and civil war owing to the contest of his two elder sons, 'Abdullah and Sa'ud, for the throne he had vacated. In 1875 the Turks occupied Hasa, while the rival dynasty of Ibn Rashid in northern Nejd gradually extended southwards until in 1891 the great Amir Muhammad put an end to the Wahhabi state by the occupation of Riyadh itself. 'Abdul 'Aziz went into exile with his family and, after a period of residence at Bahrain, arrived at Kuwait. Here he was influenced by Shaikh Mubarak ibn Sawah and to this Ibn Sa'ud owed much of his future greatness and his friendship for Great Britain. From his father he inherited steady purposefulness.

Though 'AbdulRahman was the cadet of the Wahhabi dynasty, it was he who made the first effort to recover his father's throne in 1900. His defeat at Sarif was followed by the formal abdication of his rights and obligations in favour of his eldest son, 'Abdul 'Aziz, who in 1901 launched out into the desert with a force of only 200 men. At some distance from the capital he selected 15 of these, including his cousin 'Abdullah ibn Jiluwi

(afterwards governor of Hasa), for the final venture; entering Riyadh by night with his following he forced an entry into a house opposite the great fort where the Rashidian governor was lodged. A desperate struggle left Ibn Sa'ud the master of Riyadh, where he was at once proclaimed ruler of Nejd.

During the next few years Ibn Sa'ud consolidated the outlying provinces and resisted the Turks in their support of Ibn Rashid. A Wahhabi victory at Bukairiya (1904) was followed by Ibn Rashid's death (1906) and left Ibn Sa'ud master in the house of his ancestors with no danger of interference from the north.

Free now to show his capacity for administration Ibn Sa'ud proceeded to lay the foundations of his future greatness in a scheme remarkable both for boldness and ingenuity. He boldly seized upon the latent fanaticism of his countrymen as an instrument for the creation of a non-tribal or pan-tribal element out of tribal material to leaven the mass into the semblance of a homogeneous nation. The first *Ikhwan* colony in 1912 was the first step of a deliberate programme aiming at the abrogation of the patriarchal system in Arabia in favour of nationalism. At the time such an ambition was beyond the bounds of practical politics, but circumstances combined to bring it within the focus of Ibn Sa'ud's clear vision.

'Artawiya, now a flourishing town of 10,000 inhabitants, rapidly became the prototype of a hundred colonies which sprang up in various parts of Nejd during the next 15 years. Agriculture displaced pastoral activities as the binding force of the new organization, while the *Shar'* or religious law took the place of the customary law of Badawin society. Each colony constituted a contingent of the new Wahhabi standing army, for which circumstances have provided ample work at home and abroad. It was first put to the test in 1913 when Ibn Sa'ud turned his attention to the Turks who had been in Hasa since 1875. With a mere handful of men he suddenly appeared before Hufuf, whose astonished garrison surrendered without a blow. The garrisons at 'Uqair and Qatif followed suit and the Turks left Eastern Arabia.

At the end of 1914 Captain W. H. I. Shakespear was deputed by Sir Percy Cox to visit Ibn Sa'ud with a view to enlisting his active assistance against the Turks, with whom his dynastic rival, Ibn Rashid, had thrown in his lot. Ibn Sa'ud immediately undertook military operations and in January, 1915, a battle took place at Jarrah. The result was indecisive but Captain Shakespear was killed and the British authorities were discouraged from further activity in Arabia. In December Ibn Sa'ud concluded a treaty of friendship with Great Britain but remained quiescent though he grew increasingly anxious as he watched King Husain in the Hejaz building up a strong position for himself with the help of Lawrence. In 1917 the Philby Mission visited him at Riyadh to take stock of the situation and in the autumn of 1918 Ibn Sa'ud resumed activities against Ibn Rashid. He reached the walls of Hail without being able to press home the attack, and the sudden termination of the Great War found him still within the same frontiers as at its outbreak and with two powerful enemies to reckon with, Ibn Rashid and King Husain. Relations with the latter were already strained to breaking point. In March, 1919, Lord Curzon on behalf of the British Government decided in favour of King Husain and authorised him to occupy Khurma which Ibn Sa'ud was warned to relinquish. The latter disregarded the warning and two months later the Wahhabi army surprised and annihilated the Hashimite forces at Turaba. Having vindicated his rights by might Ibn Sa'ud retired to Riyadh. In 1920 a Wahhabi expedition added the highland districts of 'Asir to Ibn Sa'ud's dominions, and in August of the following year the capture of Hail placed all central Arabia under a single rule. Meanwhile Bisha and Tathlith in the south were occupied, as also Khaibar and Taima northwards, while in 1922 Jauf came within the Wahhabi sphere.

The British Government made a belated effort to mediate at the Conference of Kuwait, convened in Nov. 1923. The discussions ended without result in April, 1924, and in September the Wahhabi invasion of the Hejaz began with the sudden capture of Taif and a massacre of its inhabitants. King Husain was forced to abdicate in favour of his eldest son, 'Ali, who evacuated

Mecca which was quietly occupied by the Wahhabis in October. The outlying districts of the Hejaz were rapidly occupied and only Jedda and Medina remained in the hands of the Hashimites, both being subjected to a desultory siege by Ibn Sa'ud who entered Mecca for the first time in December, 1924. During the following November Sir Gilbert Clayton concluded the treaties of Bahra and Hadda with him, by which certain questions relating to 'Iraq and Trans-Jordan were satisfactorily disposed of. The following month Medina surrendered, while Jedda followed suit a fortnight later. On January 8, 1926, Ibn Sa'ud was proclaimed King of the Hejaz in the great mosque of Mecca; and a year later his title of Sultan of Nejd and its Dependencies was converted to King.

Security has been established where it was never known before; motor-transport has added enormously to the comfort of pilgrims; the state revenues have increased substantially; corruption in the public service has been greatly reduced if not entirely eliminated. Relations with Great Britain were placed on a new and friendly footing by the Treaty of Jedda negotiated with Sir Gilbert Clayton in May, 1927. Unfortunately these relations were marred by a regrettable incident in November 1927. The 'Iraq government in contravention of the provisions of a protocol signed at 'Uqair (1922), had built a fort at the desert wells of Busaiya near the frontier. A party of *Ikhwan*, visiting the spot, resented the innovation and slew the builders. And the spring months of 1928 were spent in a series of futile and unnecessary raids and counter-raids, to which an end was at length put by the agreement of Ibn Sa'ud and the British Government to meet in conference. In May Sir Gilbert Clayton, since nominated to the High Commissionership of 'Iraq, again visited Jidda and the discussions, interrupted by the pilgrimage, ended in August in failure to achieve agreement on the points at issue. Ibn Sa'ud maintained unswervingly his contention that the 'Iraq Government had been at fault in building the forts in the frontier district, while the British representative was unable to agree to their demolition.

Ibn Sa'ud has now ruled 28 years in Nejd and three years over the Hejaz. His eldest surviving son and heir to the throne of his dual monarchy is Sa'ud now about 25 years old, who occupies the position of Viceroy of Nejd. The second son Faisal, who has twice visited Europe on his father's behalf, is Viceroy of Mecca. Besides these two Ibn Sa'ud has 11 other sons ranging from the age of 17 down to two. For political and other reasons the Wahhabi king has always taken the fullest advantage of Islamic laxity in the matter of marriage and divorce, and he is reputed to have been married about 150 times in the course of his career. His father, who died in June 1928, lived to see him achieve a position, perhaps unparalleled in the annals of Arabian history since the immediate successors of Mohammed himself.

(H. St. J. B. P.)

IBN TIBBON, a family of Jewish translators, who flourished in Provence in the 12th and 13th centuries. They rendered into Hebrew the chief Arabic writings of the Jews in the middle ages. These Hebrew translations were, in their turn, rendered into Latin (by Buxtorf and others) and in this way were circulated in Europe. The chief members of the Ibn Tibbon family were (1) JUDAH BEN SAUL (1120-90), who was born in Spain but settled in Lunel. He translated the works of Bahya, Halevi, Saadiah, the grammatical treatises of Janah and an ethical treatise by Gabirol. (2) His son, SAMUEL (1150-1230), translated, among other things, the *Guide of the Perplexed* by Maimonides, his friend, and wrote a philosophical treatise, *Ma'amar Yikkawu ha-Mayim* (pr. Pressburg, 1837). (3) Son of Samuel, MOSES (died 1283). He translated into Hebrew a large number of Arabic books (including the Arabic version of Euclid).

See I. Husik, *Hist. of Mediaeval Jewish Philosophy* (1916).

IBN TUFAIL or **TOFAIL** [Abū Bakr Moḥammed ibn 'Abd-ul-Malik ibn Tufail ul-Qaisī (or to the Schoolmen, Abubacer)] (d. 1185), Moslem philosopher, was born at Guadix near Granada. He was skilled in philosophy, mathematics and medicine, and was a friend of Averroes. He became secretary to the governor of Granada, and later physician and vizier to the Mohad caliph, Abu Ya'qūb Yūsuf. He died at Morocco. His chief work,

Risālat Hayy ibn Yaqzān, is a philosophical romance describing the awakening of philosophical knowledge in the intellect of a child removed from society.

See S. Munk, *Mélanges* (1859); T. J. de Boer, *Gesch. der Philosophie im Islam* (Stuttgart, 1901); L. Gauthier, *Ibn Thofāil, sa vie, ses oeuvres* (1909); Carra de Vaux, *Les Penseurs de l'Islam* (1923).

IBN USAIBI'A (MUWAFFAQUDDIN ABŪ-L-'ABBĀS AHMAD IBN UL-QĀSIM IBN ABĪ USAIBI'A) (1203-1270), Arabian physician, was born at Damascus, the son of an oculist, and studied medicine at Damascus and Cairo. In 1236 he was appointed by Saladin physician to a new hospital in Cairo, but resigned in 1237 to serve the amir of Damascus in Salkhad. There he lived and died. He wrote "*Uyūn ul-Anba fī Ṭabaqāt ul-Aṭibba*" or "Lives of the Physicians."

Edition by A. Müller (Königsberg, 1884).

IBO. A Southern Nigerian tribe comprising 33 sub-tribes, inhabiting the provinces of Benin, Ogoja, Onitsha, Owerri and Warri, whose language is related to Ibibio. The Ibo on the west of the Niger were long subject to the Edo: the rest lived in independent towns or villages under a paramount chief and a chief for each quarter. The extended family groups lived together in the same quarter. Marriage rules vary: marriage is usually prohibited between members of the same extended family and between near relations. Marriage by exchange is frequent. Descent is patrilineal. Age classes and secret societies flourish.

BIBLIOGRAPHY.—P. Amaury Talbot, *Life in Southern Nigeria: The Magic, Beliefs and Customs of the Ibibio Tribe* (1923); *The Peoples of Southern Nigeria* (1926).

IBRAHIM (d. 1536), grand vizier of Turkey, was the son of a sailor at Parga, was sold into slavery, and was bought by the sultan, Solyman II., who made him his grand vizier and married him to his own sister. Ibrahim, says a Venetian record, was "the heart and breath of the Padishah, who does nothing without consulting him; he is learned, fond of reading, and knows his law well." He was made commander-in-chief of the army for the invasion of Hungary, and in 1526 took Peterwardein. But his main functions were diplomatic. With the Venetian Gritti he conducted the negotiations for peace between the sultan and the emperor Ferdinand in 1533. In the autumn of that year he took command in Asia against the Persians. He occupied Tabriz on July 13; he was then joined by Solyman, and marched against Baghdad. In both cases he prevented plunder. They returned to Constantinople on Jan. 8, 1536. He had for 14 years been the sultan's constant companion, even sharing his sleeping apartments. They retired as usual on March 30, and in the morning Ibrahim was found strangled by the sultan's orders.

IBRAHIM AL-MAUSILĪ (742-804), Arabian singer, was born of Persian parents settled in Kufa. In his early years his parents died and he was trained by an uncle. Singing, not study, attracted him, and at the age of twenty-three he fled to Mosul, where he joined a band of wild youths. After a year he went to Rai (Rei, Rhagae), where he met an ambassador of the caliph Manṣūr, who enabled him to come to Baṣra and take singing lessons. His fame as a singer spread, and the caliph Maḥdī brought him to the court. There he remained a favourite under Hādī, while Harūn al-Rashīd kept him always with him until his death, when he ordered his son (Ma'mūn) to say the prayer over his corpse. His powers of song were far beyond anything else known at the time.

See the Preface to W. Ahlwardt's *Abu Nowas* (Greifswald, 1861), pp. 13-18, and the many stories of his life in the *Kitāb ul-Aghānī*, v. 2-49.

IBRAHIM PASHA (1789-1848), Egyptian general, son, or adopted son of Mohammed Ali, pasha of Egypt, was born at Kavala in Thrace. During his father's struggle to establish himself in Egypt, Ibrahim, then sixteen years of age, was sent as a hostage to the Ottoman capitan pasha (admiral), but when Mohammed Ali was recognized as pasha, he was allowed to return to Egypt. When Mohammed Ali went to Arabia to fight against the Wahhabis in 1813, Ibrahim was left in command in Upper Egypt. He continued the war with the broken power of the Mamelukes, whom he suppressed. In 1816 he succeeded his brother Tusun

in command of the Egyptian forces in Arabia. Mohammed Ali had already begun to introduce European discipline into his army, and Ibrahim had probably received some training, but his first campaign was conducted more in the old Asiatic style than his later operations. The campaign lasted two years, and the political power of the Wahhabis was destroyed. Ibrahim landed at Yembo, the port of Medina, on Sept. 30, 1816. The holy cities had been recovered from the Wahhabis, and Ibrahim's task was to follow them into the desert of Nejd and destroy their fortresses. Such training as the Egyptian troops had received, and their artillery, gave them a marked superiority in the open field. But the difficulty of crossing the desert to the Wahhabi stronghold of Deraiya, some 400 m. east of Medina, and the courage of their opponents, made the conquest a very arduous one. Ibrahim displayed great energy and tenacity, sharing all the hardships of his army, and never allowing himself to be discouraged by failure. By the end of September 1818 he had forced the Wahhabi leader to surrender, and had taken Deraiya, which he ruined. On Dec. 11, 1819, he made a triumphal entry into Cairo. After his return he supported the Frenchman, Colonel Sève (Suleiman Pasha), who was employed to drill the army on the European model. Ibrahim set an example by submitting to be drilled as a recruit.

When in 1824 Mohammed Ali was appointed governor of the Morea by the sultan, who desired his help against the insurgent Greeks, he sent Ibrahim with a squadron and an army of 17,000 men. The expedition sailed on July 10, 1824, but Ibrahim was not able to land at Modon until Feb. 26, 1825. Ibrahim easily defeated the Greeks in the open field, and though the siege of Missolonghi proved costly he captured the place on April 24, 1826. The Greek guerrilla bands harassed his army, and in revenge he desolated the country and sent thousands of the inhabitants into slavery in Egypt. These measures led first to the intervention of the English, French and Russian squadrons (see NAVARINO, BATTLE OF), and then to the landing of a French expeditionary force. By the terms of the capitulation of Oct. 1, 1828, Ibrahim evacuated the country. English officers who saw him at Navarino describe him as short, grossly fat and deeply marked with smallpox. In 1831 Ibrahim was sent to conquer Syria. He took Acre after a severe siege on May 27, 1832, occupied Damascus, defeated a Turkish army at Homs on July 8, defeated another Turkish army at Beilan on July 29, invaded Asia Minor, and finally routed the grand vizier at Konia on Dec. 21. The convention of Kutaiah on May 6 left Syria for a time in the hands of Mohammed Ali.

After the campaign of 1832 and 1833 Ibrahim remained as governor in Syria. The exactions he was compelled to enforce by his father soon provoked revolts. In 1838 the Porte felt strong enough to renew the struggle, and war broke out once more. Ibrahim won his last victory for his father at Nezib on June 24, 1839. But Great Britain and Austria intervened to preserve the integrity of Turkey. Their squadrons cut his communications by sea with Egypt, a general revolt isolated him in Syria, and he was finally compelled to evacuate the country in February 1841. In 1846 Ibrahim paid a visit to western Europe. When his father became imbecile in 1848, he held the regency till his own death on Nov. 10, 1848.

See Edouard Gouin, *L'Égypte au XIX^e siècle* (Paris, 1847); Aimé Vingtrinier, *Soliman-Pasha (Colonel Sève)* (Paris, 1886). A great deal of unpublished material of the highest interest with regard to Ibrahim's personality and his system in Syria is preserved in the British Foreign Office archives; for references to these see *Cambridge Mod. Hist.* x. 852, bibliography to chap. xvii.

IBSEN, HENRIK JOHAN (1828-1906) Norwegian poet and dramatist, was born at Skien on March 20, 1828. His father, Knud Henriksen Ibsen, a merchant, was of mixed Danish, German and Scotch blood; his mother, Maria Cornelia Altenburg was a Norwegian, of German descent. When Ibsen was eight years old, his father failed in business, and recollections of the penury which followed can be found in *Peer Gynt*.

Early Life and Works.—At the age of 15 Ibsen was apprenticed to an apothecary in Grimstad, a small town of eight hundred inhabitants; it was a business he detested, and he began to express himself and relieve his misery by writing poetry in 1847.

He read widely and deeply, especially in poetry and theology, and in 1850 he went to Christiania as a student; this year also saw the publication of his first play, a blank-verse tragedy, *Cataline*, which was followed, not many months after, by *The Viking's Barrow*, which was performed at the Christiania theatre, but not published. For a few months he co-operated in the production of a weekly satirical newspaper; but in November 1851, when in September the paper's brief life of nine months had ended, he was appointed as "theatre-poet" to the new theatre at Bergen, established for the encouragement of Norwegian drama, by the violinist Ole Bull. This position Ibsen held until the summer of 1857, and this intimate connection with the theatre—he combined the duties of producer, manager, adviser and designer with that of a poet—confirmed him in his nascent desire to be a dramatist. The plays which he wrote for this theatre were *St. John's Night* (1853), *Lady Inger of Ostrat* (1855), *The Feast of Solhaug* (1856) and *Olaf Liljekrans* (1857). He left Bergen for Christiania in 1857; and his next two plays reflect the influence of his engagement and marriage to Susanna Thoresen; *The Vikings of Helgeland* (1858) and *Love's Comedy* (1862) are the first plays—earlier signs may be found in the lyric poems—in which the unmistakable voice of Ibsen is heard clearly. Both plays were misunderstood; and the fierce anti-romantic, idealistic satire of *Love's Comedy* caused a storm of indignation in Denmark and Norway: it is Ibsen's earliest protest on behalf of the inalienable rights of the individual, his first stroke in the life-long battle against the stupidity, the weight of the majority. There is in it not a little of the spirit which we find in the satiric poetry of Arthur Hugh Clough whose lines "O let me love my love unto myself alone And know my knowledge to the world unknown," might well have been Henrik Ibsen's motto. He had accepted the position of manager of a new theatre in Christiania; but he could not get *The Vikings* produced there, and it was not acted until 1861. The next year his theatre failed, and Ibsen became adviser in aesthetics at the opposition house. In spite of his disappointment and the disgust he felt at the reception of *Love's Comedy* he wrote for this theatre *The Pretenders* (1864), the best drama of his saga period. It was a popular success; but the managers of the Christiania theatre were shy of its strangeness, and it was not until Ibsen's reputation was secure—after the publication of *Brand* and *Peer Gynt*—that it took its place as one of the masterpieces of the new theatre.

Ibsen had applied to the Storting for a poet's pension, which had been recently given to Björnson; but it was refused and in indignation he went into exile; for his departure to Italy in 1864 was not an ordinary tour to the sun and the south. It was undertaken with a deep sense of injustice, which was partly responsible for the two magnificent poetic dramas—*Brand* (1866) and *Peer Gynt* (1867). After the issue of *Brand* he was granted a poet's pension and Ibsen had no longer to fear actual penury.

Plays.—In 1869 he wrote the earliest of his modern prose dramas *The League of Youth*, a political satire that roused as much animosity as did *Love's Comedy*; he was now settled in Dresden, but he returned to Norway for a short time after the publication of one of the most ambitious dramas ever composed—the huge double play *Emperor and Galilean* (1873), an elaborate historical study of the character of Julian the Apostate, which shows wide reading and a remarkable power of re-creating familiar figures of history. It is of great interest as one of the first attempts to free the study of Greek history from that smooth, neo-classical veneer by which it was falsified; it is far nearer in spirit to the Greece of Gilbert Murray and Jane Harrison than the Hellas of Winckelmann or Shelley. These years also mark the end of Ibsen's work as a poet; his collected lyrics were published in 1871, and the occasionally exalted prose of *Emperor and Galilean* does not again reappear in his work, except in brief snatches in some of the later prose dramas. His deep interest in politics was made intenser by the growing power of Germany, and when the days of the Commune came in Paris he felt strong in him something of the hopes that had awakened in 1848, when there was promise of revolution in Europe. His only persistent political principle, to be found in every play from *The Pretenders*

to *When We Dead Awaken*, was the necessity of a society which should give the amplest possible opportunity for the free growth of the individual, and he was naturally and inevitably disappointed with all movements of reform—liberal, radical, socialist—as conducted. He found that they all tended in time to subordinate the individual to the state—and to Ibsen the state, the great compact majority, was always the enemy. In 1877 he published *The Pillars of Society*—a title which might be taken to cover all the social dramas which succeeded that play.

Later Life.—Ibsen's life presents few points of interest except the steady production of his plays; he never had the inclination nor the necessary social exuberance for such public and political appearances as were enjoyed by his rival and contemporary Björnson. From 1868 to 1891 his permanent home was Germany, first in Dresden, later in Munich; in 1891 he settled in Christiania where he lived till his death on May 28th, 1906; for the four years previously he had suffered from an almost complete physical and mental collapse, and was unaware of the world without. Of his marriage (1858) there was one son, Sigurd, to whose education Ibsen devoted no little care and thought. When he left his home in 1850, he ceased to communicate with any of his family except his sister Hedvig; and although he had friends in journalism and in the theatre there is little evidence that any one had any real or permanent influence on the development of his character and his genius; he was grateful to Björnson, he was grateful to Brandes, for the support each gave him at different periods of his career, but he never showed the slightest inclination to accommodate his own thought to their ideas. No other dramatist of so immensely creative a genius has ever been so lonely: he did not need long or continuous intercourse with society. A chance word, a chance meeting, a sudden memory were enough to fertilize that powerful imagination which then, feeding on itself and nourishing the germ, gave birth, every two years, to a play which brought into the world entirely new characters, owing only an infinitesimal part of their life to any power outside the mind and spirit of the dramatist. Ibsen was first and last a great poet, and a great mystic—one of the greatest poets and the greatest mystics who ever devoted himself to the drama; the "lyrical Pegasus" may as Brandes said, "have been killed under him," but his poetic inspiration burned all the more fiercely because of the severe limits which Ibsen forced on its expression, limits which are unfortunately very much exaggerated in the best-known English versions of his social dramas. His interest in his characters, real as they are, intense as it is, is always dependent on his poetic vision of life; his vision of life is never dependent, as was Björnson's, Strindberg's or even Goethe's, on circumstances either of his own choosing or of chance. Ibsen was never afraid that facts, however obstinate, or persons, however powerful, could detract from the truth and his grasp of it. In this he showed signs of affinity to the theological outlook on the world. He knew, mystically, that his conception of life and of mankind could explain and express all the facts with which he came in contact; and if ever he met apparent contradictions, he was ready to dismiss them as irrelevant or worthless. His consummate skill as a dramatist, his influence in the making of a new European theatre must not allow us to forget that he was never of the movement which he caused, and of which he was acclaimed the leader. He was always in advance and always detached.

Main Ideas.—There are two main ideas in Ibsen's work, implicit even in the early dramas, and explicit, in different degrees of emphasis, in his theatre from *Brand* to *When We Dead Awaken*. Of this continuity in his work he was himself fully conscious, and resented the tendency to separate his work into periods, and find any contradiction—except a purely formal one—between the laughing, rapid poetry of *Peer Gynt* and the close, compact prose of the social dramas. The two ideas are these. First, the supreme importance of individual character, of personality: in the development and enrichment of the individual he saw the only hope of a really cultured and enlightened society. Second, comes the belief that the only tragedy that can be suffered, the only final wrong that can be committed, is the

denial of love. The former idea was easily grasped, and was proclaimed by most Ibsenites—Brandes, Archer, and Shaw—as the key to Ibsen's drama; the latter idea was excused in the poetic plays as a relic from an imaginary romantic phase of Ibsen's life, and ignored when it appeared again in the social dramas, especially the later ones. Archer indeed was so disturbed at its very evident intrusion in *When We Dead Awaken*, that he suggested that the dramatist's mind was already failing; while he followed Shaw in his description of the climax of *Peer Gynt* as a "crowningly unreal self-realization." The reason for this obtuseness—shared by nearly all early critics of Ibsen except Sir Arthur Quiller-Couch—is to be found in the fact that it was the lot of Ibsen, a Christian mystic with no definite allegiance to any religious body, to be interpreted to the world by men who were mostly sentimental rationalists, who noticed, what was fully obvious, that the dramatist waged an unceasing war against conventional Christianity, but failed to observe that he did so, not under the banner of rationalism, but in the name of an intenser Christianity.

The same mistake was made, and is still made occasionally, by interpreters of William Blake, in whose thought may be found not a little which would have won Ibsen's sympathy and understanding. In *Brand* Ibsen preached his first and most defiant proclamation of the need of whole-heartedness in the personality; the prophet-priest of the play with his cry of "All or nothing," is a projection of Ibsen's own character, with its stern refusal to be diverted from his work. Balancing that play is *Peer Gynt*, the richest, the most imaginative and fantastic of Ibsen's works: as Brand stands for singleness of purpose, *Peer Gynt* is the embodiment of distraction and dreaming—a parody in some sense of Ibsen's own gospel that facts do not matter, anticipating the bitterer parody of *The Wild Duck*.

In *A Doll's House* (1879) we have the first emphatic statement of Ibsen's individualistic creed. It is not a feminist play. Ibsen was at the moment pre-occupied with the struggle between society and the individual, and he chose a woman as his protagonist because he knew that, on the whole, women were more likely to take a personal view of life than men. There are two dramas in the play—one consists in Nora's discovery that she has lived for years with a strange man; but this depends on the more essential drama that for Torvald a crime against society is more important than a sin against love. The same motive inspired, in a more terrible form, *Ghosts* (1881); and when *Ghosts* roused fury throughout Europe, Ibsen retorted on his critics with *An Enemy of the People* (1882) in which he attacks the stupid majority who prefer disease to the confession of their disgrace. One of the loveliest of his plays, one in which the poet breaks out again, is *The Wild Duck* (1884). It has a tenderness and a lyrical beauty which stand out all the more strongly beside the fierce satire against those who have misinterpreted him. This play, with its quiet charm, its ironic humour and its devastating satire, is the record of Ibsen's discovery that it takes two people to tell the truth, one to speak and one to understand what is spoken—the last lesson to be learned by all prophets.

Later Works.—*Rosmersholm* (1886) written after a journey to Norway is a powerful study in ineffective idealism—and in the contrast of Rebecca West and Rosmer Ibsen reached his greatest heights in pure tragedy. *The Lady from the Sea* (1888) is the happiest of the prose dramas; it is rather weak in construction, but its characterization has a cheerful, relenting quality, and Dr. Wangel is one of the few men who can be put on a level with Ibsen's women. Of all modern plays Ibsen's come nearest, in form and sense of necessity, to the theatre of Athens; and of all his plays *Hedda Gabler* (1890) is, with the possible exception of *Ghosts*, the nearest to the Greek. If Hedda had been called Medea, her egotistic ferocity would not perhaps have so distressed those critics who pitifully complained that Ibsen's women were not womanly. *The Master Builder* (1892) is a return to the poetic, symbolic manner; and the conflict between two generations, Solness and Hilda, has become a classic statement of an age-long problem. *Little Eyolf* (1894) and *John Gabriel Borkman* (1896) are variations on his old theme, the conflict between

love and the claims of other desirable things. In *Little Eyolf* love is threatened by the lust of the woman and by the vanity and incompetence of the man; the solution comes only through disaster; in *John Gabriel Borkman* love has been killed by ambition, and with love dead, there is nothing else; and the end of the play is the dramatist's consummate disclosure of the truth that Borkman, Ella and Gunhild were dead before the play opened, and that none of the other characters, except the old clerk Foldal (one of Ibsen's most exquisite minor characters) has ever been alive. Yet there is hope *When We Dead Awaken* (1900). This great final statement of the poet's invincible creed has disappointed those who had misunderstood his earlier plays, and attached too much importance to the incidental social teaching that can be extracted from them, and to their amazing stagecraft. Its form is less perfect, its external action fantastic; but in the reunion of Rubek and Irene Ibsen writes out of his very soul, repeating once more his persistent cry that, whether the world be well lost for love or no, at least that which a man thinks to gain by the sacrifice of love is not held at all.

The intense reality of Ibsen's characters, while evident at a first reading or a first hearing of any play, can only be properly appreciated by continuous study of his complete theatre. It was his habit to make more or less complete histories of the lives of his people up to the moment of the opening of the first act; and in the drafts and first version of many plays (available in the volume called *Ibsen's Workshop*) can be seen the care with which he worked, the fierceness with which he sacrificed anything, however entertaining, that was not essential, and his amazing power of getting the utmost out of a character or a situation. He made his people work for him; and there is no dramatist in whose work it would be so hard to find a single speech out of character. He could not bear either to discuss, or to disclose, the idea of a new play until it was completed. He retired into his own world with his own people, and agonized until they became and did exactly what he knew was right. When, as in *The Lady from the Sea*, he relaxes a little, the change in atmosphere is startling. This severity might be lamented as a defect did we not know from *Peer Gynt* that it was a deliberate sacrifice. The author of that supremely diverting and supremely mobile play cannot be accused of any incapacity for exuberance.

Ibsen's later abstinence from humour, from divagations and those extravagances which charm us in *Peer Gynt* was the abstinence not of impotence but a deliberately self-imposed control. It may be that he sometimes regretted his choice, for in 1900 he wrote to Count Prozor (after the publication of *When We Dead Awaken*) that, if he comes back to the old battlefields, "it will be with new weapons and in new armour"; there was, however, to be no reappearance, and it would indeed be ungracious for the world to complain of any lack of variety in the drama of the man who left us *Brand*, *Peer Gynt*, *Emperor and Galilean*, *A Doll's House*, *The Wild Duck*, *The Master Builder* and *When We Dead Awaken*.

IBYCUS, of Rhegium in Italy, Greek lyric poet, contemporary of Anacreon, flourished in the 6th century B.C. He lived a wandering life, and spent a considerable time at the court of Polycrates, tyrant of Samos. Plutarch (*De Garrulitate*, xiv.) preserves the legend of his death. Attacked by robbers, he called on a flock of cranes to avenge him. Later, one of the robbers, in the theatre at Corinth, saw the cranes, and said "Behold the avengers of Ibycus," thus betraying himself. The "cranes of Ibycus" became proverbial. Ibycus wrote seven books of lyrics, partly mythical, but mainly erotic (Cicero, *Tusc. Disp.* iv. 33).

The best editions of the fragments are by F. W. Schneidewin (1833) and Bergk, *Poëtae lyrici Graeci*.

ICA, a coast department of southern Peru, bounded on the north by the department of Lima, east by Huancavelica and Ayacucho, south by Arequipa, west by the Pacific. It includes the western slopes of the cordillera and desert coast zone, a barren waste except for fertile, irrigated valleys of the Chincha, Pisco, Ica and Grande rivers. Pop. (estimate 1920), 90,962; area, 9,799 sq.m.

In the Chincha valley, of which Chincha Alta (pop. 6,000) is the chief town, 35,000 ac. are under cultivation—the cotton yield second only to Piura—25,000 in the Pisco valley, and 12,000 in valleys tributary to the Rio Grande. The Pisco valley is the home of Señor Fermin Tangüis, originator of the cotton which bears his name, a variety which is gradually replacing the cultivation of others in Peru. The Nazca valley, tributary to the Grande, has a pre-Hispanic irrigating system and is famous for its archaeological remains. A system of roads including the coast trunk-line, 25–35 m. inland, is finished, though sometimes sand-covered, throughout its length, 214 m. Several branches run up the valleys to agricultural centres, a total of 404 miles of finished roads (1927). A railway 46 m. long connects Ica, the capital, with its port, Pisco. The only other port is Tambo de Mora, 16 m. north of Pisco, connected with Chincha Alta by rail (7½ m.). Chief products of the department are cotton, grapes, wines, spirits, honey, tropical fruits and vegetables. Lake Huacachina, near Ica, is a famous health resort.

Ica, a city, capital of the department of the same name, is 46 m. by rail south-east of its port, Pisco. Pop. (estimate 1927), 13,000, altitude 1,300 feet. It lies in an irrigated valley filled with vineyards and cotton fields (total producing area about 50,000 ac.). Much of the brandy known as "Pisco" is produced in the Ica valley. The original town (founded 1563), has been twice destroyed by earthquake and looted by a Chilean army in 1882. In spite of repeated disaster, it has typical Spanish charm and considerable commercial and industrial activity. Imports are controlled by wholesale houses, and several Lima banks have agencies here. The largest industry is a cotton factory including gin, oil-mill and other departments. (M. T. Br.)

ICE is the solid formed when water freezes. It is a colourless substance crystallizing in the hexagonal system (*vide infra*); the crystals display a marked tendency to "twinning," and this is what gives rise to the flower-like patterns so frequently noticed on windows. Hoar-frost, snow and hail result from the freezing of atmospheric moisture.

The temperature of melting ice is adopted as a standard in thermometric scales, being zero for both the Réaumur and Centigrade scales, and 32° for the Fahrenheit.

In the act of freezing, water undergoes a remarkable expansion although its temperature remains unchanged; consequently, ice at 0°C. has a density only 0.9175 of that of water at the same temperature, and therefore floats on cold water. If the ice were denser than the water, it would sink and ponds would then freeze from the bottom upwards, thus becoming solid much more rapidly than they do; this low density of ice is thus of great significance to pond life and therefore indirectly to all life.

The process of freezing in a pond presents features of interest. If the air is at or below 0°C. and the temperature of the water is, say, 10°C., the upper layers of water become colder and sink into the main bulk, since the cold water is denser than the rest; this process continues until the whole of the water is chilled to 4°C., but at this temperature it attains its maximum density (*see WATER*), and thereafter the surface layers, having a lower temperature than 4°C., are relatively lighter, remain on the surface and begin to freeze. The freezing is facilitated by the stillness of the water, resulting from the cessation of convection currents below 4°C. Sea water does not freeze until it is cooled to about -2°C., even in the most favourable circumstances, and the resulting ice is found to be practically free from the salt present in the water.

On being cooled, ice behaves like most other solids and contracts; its specific heat is about half that of water. In order to

melt ice at 0°C. into water at the same temperature, it is necessary to supply a definite quantity of heat, viz., 80 calories per gram; this is called the "latent heat of fusion," since its absorption causes no rise of temperature. Conversely, the same amount of heat has to be dissipated during the freezing of water. In 1849 James Thomson showed that, since water expands on freezing, according to the laws of thermodynamics its freezing point must

be lowered by increase of pressure, and he calculated this lowering to be 0.0075° per atmosphere, an estimate subsequently verified by his brother, Lord Kelvin. When two blocks of ice at 0°C. are pressed together, the ice melts at the point of contact, the flow of resulting water relieves the pressure, and the water freezes again; these processes continue until the blocks are firmly united. A similar explanation accounts for the movements of a glacier past restrictions in its course—the pressure causes local melting and flowing, and the ice gradually adjusts itself to the constriction and refreezes on the farther side.

STRUCTURE OF ICE
White spheres represent the effective volume of oxygen atoms; black spheres, hydrogen atoms

In India water is made to freeze on cold clear nights by leaving it in a porous vessel (*Chatti*), the evaporation from the pores absorbing sufficient heat from it.

Ordinary block-ice is rendered opaque by minute bubbles of air which are produced in any but very slowly cooled water, owing to the decreased solubility of the air.

By subjecting ice to enormous pressures, P. W. Bridgman and G. Tammann have produced four other forms of ice (five according to the latter) differing in crystalline form and in density, all being denser than water. Thus, ordinary ice (Ice-I) at -10°C. is converted under 4,400 atmos. to Ice-V, and at 6,300 atmos. to Ice-VI; similarly, at -30°C. 2,200 atmos. pressure converts Ice-I to Ice-III, and 3,000 atmos. converts it to Ice-II, and higher pressures then produce Ice-V and Ice-VI.

The crystal structure of ice has been investigated by several workers. That deduced by Sir W. H. Bragg (*Proc. Physical Soc.*, 1922, 34, p. 98) is shown in the annexed diagram, from which it will be seen that, when the structure is extended indefinitely in all directions, each oxygen atom is situated at the centre of gravity of four equidistant oxygen atoms, from each of which it is separated by a hydrogen atom. Thus, each hydrogen atom touches two oxygen atoms and each oxygen touches four hydrogens. The whole structure agrees with the hexagonal habit characteristic of the crystals, and its open nature accounts for the low density of ice, which is exactly that calculated from the dimensions given. (For the manufacture of ice, *see REFRIGERATION*.) (A. D. M.)

ICE AGE: *see GLACIAL PERIOD and PLEISTOCENE.*

ICEBERG, a floating mass of ice broken from the end of a glacier or a polar ice-sheet. Icebergs drift according to the direction of the sea currents, frequently from the polar regions to navigable waters, and they are therefore occasionally encountered far beyond the polar regions. When a glacier descends to the sea and is pushed outwards into water of greater depth than the thickness of the ice, the ends are broken off and the detached masses float away as icebergs. Only one-ninth of the mass of ice is seen above water. Many bergs are overturned, or at least tilted, as they set sail, as the result of the wave-cutting and melting which disturb their equilibrium. The disintegration of an Arctic ice-sheet is a simpler matter, as the ice is already floating. The ice-sheet cracks at the end, and masses break off, owing to the upward pressure of the water upon the lighter ice. This is accomplished with considerable violence. Icebergs, especially those of glacier origin, carry a load of débris which they gradually strew upon the sea floor; glacial material found in dredgings shows that icebergs occasionally transport their load for a considerable distance.

ICE-CREAM. A name applied to a great variety of frozen compounds, ranging from a cheap mixture of custard powder, water or milk, sugar, flavouring and colouring matter, to real

cream compounds, soufflés and parfaits, water ices and "sorbets," ice-cream blocks, etc. Ice-cream making is an important branch of the confectionery and because of its excellent food value has taken an important place in the diet of some people. The necessary utensils for a small trade, or for household use, are pewter freezers in wooden tubs or any good ice-machine (there are many on the market), pewter spatulas, ice pick, ice caves for storing or sending out ices, and pewter moulds, which are made in many shapes and sizes, for ice puddings or for small ices to serve to one person. The common American freezers are made with metal cans which revolve in a wooden tub and have a paddle which revolves inside the can.

The most usual freezing mixture employed is of coarse freezing salt and ice, about one-third of salt to two-thirds of ice; more salt may be used if a very sharp frost is needed, but too much salt melts the ice. The ice is broken with the ice pick into pieces not smaller than a large walnut. The freezing mixture is used in layers in a tub. Care must always be taken that no salt gets into the mixture. The paddle or spatula is used for mixing and to maintain a smooth creamy mixture.

Varieties of Ice-cream.—(1). Cream ices may be flavoured with vanilla, chocolate, caramel, coffee, strawberry, raspberry, orange, or in fact any fruit. They are made from cream, fruit purée or flavouring which gives the name to the ice, with sugar and colouring. Half cream and half custard may be used, or for a very economical ice, custard without cream. *Standard proportions:* $\frac{1}{2}$ pint fruit purée, $\frac{1}{2}$ pint cream (or $\frac{1}{4}$ pint custard and $\frac{1}{4}$ pint cream). Before serving moulded ices, the mould should be passed under cold water, so that the ice will slip out of the mould when it is unfastened.

(2). *Soufflés, Mousses, Parfaits.*—These are not frozen in ice-machines. For soufflés the mixture is put into large or small soufflé cases, for mousses into bombe moulds, and placed in an ice cave to become cold. When packed with the freezing mixture the cave should be covered with coarse house-flannel or blanket. Parfaits are flavoured with liqueurs and fruit purées.

(3). *Water Ices, Sorbets.*—There are many varieties, viz., lemon, orange, jam, pineapple, strawberry, or indeed any fruit, and tea. Sorbets are flavoured with liqueur and frozen rough. *Standard proportions:* $\frac{1}{2}$ lb. loaf sugar and 1 pint of water boiled for syrup, 1 gill fruit juice and the white of two eggs.

Factory Ice-cream.—Both in the United States and Great Britain ice-cream is made in great volume for popular consumption. Ice-cream, sold in large quantities, is made from a standard mixture of milk, cream and sugar, to which flavourings and colouring-matters are added. Eggs and custards are also used in some of the factory sorts.

The mixture is first sterilized in enormous vats. By means of large pipes this is passed through a cooling chamber into vats holding 100 gal. each and is kept moving until cold. It then rests for 24 hours, when the creamy mass is again passed through large pipes into vessels, whence it is easily poured as needed into large cylindrical pans, which are taken on trolleys into freezing rooms. Machinery is so arranged that hands never touch the ices. (E. G. C.)

In America the mixture is first standardized in a tank and packed into pasteurizers where it is held for a period of time at about 148° in order to kill harmful bacteria. The mixture then passes through a machine known as the "homogenizer" or "viscolizer," which breaks up the globules of fat and makes for a smoother product. The mixture is still hot and must be cooled and in order to do this quickly it is dropped over the outer surface of a series of pipes containing cold brine. These pipes are arranged one above the other so that there is a fall of about 8 ft., during which the temperature is lowered about 100°. It next passes into tanks, holding usually about 1,000 gal. each, in which a revolving coil operates to keep the mix in motion until ready to be frozen. From these holding tanks, or "agitators," the mix passes to the room where the ice-cream freezers are placed. The sugar is placed in the mix in the standardizing room and the flavour is added to the mix at the freezer. The freezers or containers are placed in a hardening room, constructed of concrete

and lined with cork. The temperature, controlled by a brine refrigerating system, ranges from 10 to 20 degrees below zero. The cans and moulds from the freezer rooms, placed in the hardening room, are shipped directly out to the retailer. There are two generally accepted grades of ice-cream; Philadelphia, which is cream, sugar and flavour; and French, which is practically the same formula but to which has been added a heavy custard.

ICE HOCKEY, a game dating probably from the 18th century. In the mid-Victorian age the players, four or five a side, used curved hockey sticks and a bung.

From stick and bung the game evolved to "bandy" or hockey-stick and ball, usually the lacrosse ball of solid rubber, mainly through the agency of the Bury Fen team and the brothers Tebbutt, rivals of the famous Virginia Water club founded in 1873 by H. Blackett. In 1891 the Bandy Association was formed and the game fairly established as a national pastime. International matches, 11 a side, were also started with the Dutch in 1891, a Bury Fen team captained by C. G. Tebbutt defeating Haarlem by 14 goals to 1, while in 1893 the latter turned the tables by defeating the English 7-1. The Tebbutts introduced the game into Scandinavia, visiting Norway, Sweden and Denmark. Meanwhile Switzerland was the scene of annual matches among the fast increasing British visitors, especially at the two oldest centres, Davos and St. Moritz.

Such games were played on large grounds up to 200 x 100 yd, with any number from 7 to 11 players. Meanwhile the combined influence of the Niagara club in Westminster, of Prince's club at Prince's skating rink, Knightsbridge, and the Oxford Canadians—the fickleness of the British climate, making regular bandy almost impossible except at the favoured Swiss resorts with the consequent multiplication of indoor rinks—and finally the immense development of the game in Canada and America (see below) in preference to bandy were causing a rapid revolution in favour of the more popular form of the game known as ice hockey.

The essential difference is that this game is played with a "puck" or flat solid circular disk of vulcanized rubber, 3 in. (7.62 cm.) in diameter by 1 in. (2.54 cm.) thick, weighing about 5-6 oz. (141.5-170 gr.), and with no more than six players a side. Further, the "field of play" is enclosed by wooden barriers, often 40 in. high from the ice, the "goal-cage" enclosed with netting 4 ft. (1.22 metres) in height with posts 6 ft. (1.83 metres) apart being placed 13-4½ metres from the end of the ice so that it is possible to skate round behind the goals. The result is that in contradistinction to other ball games the puck is very seldom out of play, and this added to the lightning speed at which the game is played has given rise to the claim that ice hockey is the fastest of all games, as well as the most strenuous and exhausting. The limits of the arena are fixed at a maximum of 80 x 40 metres, usually 60 x 25 metres, a convenient size for most indoor rinks. That of the new Ice club in London, for instance, is 170 by 90 ft., enclosed by netting to protect spectators, while the Richmond Ice Rink club, opened in 1928, with its surface of 286 x 85 ft., is even larger.

The rules of play emanated from Canada and have been drawn up by an International Ice Hockey League, to which the following 16 nations belong: Great Britain, Canada, United States, Belgium, France, Germany, Austria, Italy, Switzerland, Finland, Poland, Hungary, Rumania, Sweden, Spain and Czechoslovakia.

In 1927 the championship of Europe was won by Austria in Vienna, and the double championship of Switzerland by Davos, but the outstanding feature of the season was the victorious tour of the Victoria Ice Hockey club of Montreal, representing Canada. Their victories included Stockholm, Viborg, Djurgarden (champions of Sweden), Soedertaelja, Berlin, Czechoslovakia, Vienna, Wiener Eislauf-Verein, Milan, Switzerland, Davos and St. Moritz, Cortina d'Ampezzo, without a single defeat, their goal total being 171-10, while they concluded with a 14-1 victory in London over an England side drawn from the London Lions, the universities, Prince's and Manchester clubs—a remarkable record.

In Feb. 1928 ice hockey matches were played in the Olympic Games at St. Moritz, with the following final placings: 1—Canada; 2—Sweden; 3—Switzerland; 4—Great Britain. Eleven nations entered, Canada, the winners of the previous

DETAILS OF PLAY IN ICE HOCKEY

1. Ice hockey match, showing action at cage. Player in striped uniform is attempting a shot at goal (left). Player in dark uniform is making a sweep check to break up the play. Goal keeper, standing in front of cage, is trying to prevent the scoring of a goal. Man behind cage is the goal umpire
2. Practising ice hockey at St. Moritz, Switzerland. Player at extreme right is driving the puck or rubber disc, attempting to score a goal, and is about to shoot the puck. Goal keeper is in defensive position. Sideboards of rink and construction of goal are clearly shown
3. Goal keeper wearing full equipment for hockey match. Player stick shown is wider than that used by other players on the team. The protective leg pads prevent injury from the puck, which is driven toward the goal with great force by players of the opposing team. Pneumatic or padded chest protector is used to protect the body
4. Player illustrating left-handed pose, in position for shot at goal. The puck is shown at blade of stick. Leg and knee pads are worn, as well as padded gloves and trunks, and chest and shoulder padding
5. Player in left-handed position to block or check opponent
6. Player in right-handed position to play the stick and puck from right side of the body
7. Player in position to pass puck to teammate on combination play

Olympic matches at Chamonix in 1924, being required to play only the winners of the three groups. The Canadians who played magnificently, beat Sweden 11-0, Switzerland 13-0 and Great Britain 14-0. They subsequently on tour beat Davos 6-1, Paris 6-0 and England 11-4.

THE UNITED STATES AND CANADA

Every tiny hamlet throughout the Dominion of Canada has its hockey rink laid out in the open air during the winter months, but the larger cities are equipped with substantial buildings in which the game may be played before large gatherings of spectators. Despite the fact that frost is almost continuous in the winter months in most parts of Canada, east of the Rocky mountains, many of the city rinks are equipped with artificial ice plants which guarantee an ice surface before the winter really sets in and after the spring has begun.

There are six players to a team, the positions being goal, left defence, right defence, centre, left wing and right wing (forwards). The centre of the rink is marked and the teams take positions on either side of this centre point, nearest the goal they are defending. The goal-keeper takes a position directly between the posts of the goal net. The defence men take positions to the right and left of the goal net about 25 ft. towards the centre of the ice from the net. The forwards take positions on a line close to the centre of the ice. The game is started by a referee dropping the puck between the opposing centres in centre ice. This puts the puck in play, and the opposing teams must keep "onside," or behind the puck, when pushing or passing it from one player to another in combination play. The passing between members of the same teams may be intercepted at any time by an opponent.

There is some difference between the professional and amateur rules, but the usual play is for three 20 min. periods with 10 min. intermissions between periods. Substitutes may enter the play at any time, but no substitution may be made unless the player being replaced leaves the ice. A goal is scored by the puck being driven fairly into the net or across the goal line by a stick. The team scoring the most goals in the three periods of play is declared the winner. In the event of a tie when the regulation number of periods is completed, overtime sessions are played. The present professional rules call for two "sudden death" periods of 5 min. each. If either team scores in these overtime sessions, the game is immediately over, but if neither team is able to score, the contest is declared a draw. Penalties are imposed by the referee for tripping a player, slashing with the stick, checking a player bodily with undue roughness, or by unfair use of the stick. The player penalized is sent to the sidelines, and takes no part in the game for such time as the referee sees fit to penalize him. A minor penalty is 2 min., a major penalty is 5 minutes. The penalized player's team continues to play short of his services until the expiration of the time of his penalty.

The National Hockey League is the major professional league. The teams comprising this circuit represent the following cities: two from New York, two from Montreal and one each from Toronto, Ottawa, Boston, Chicago, Detroit and Pittsburgh. The amount paid for admissions for the season 1927-28 at National Hockey League games was \$1,304,683. Players are purchased by the teams, prices ranging from \$5,000 to over \$30,000. The average salary of a major league player is approximately \$4,500 per season.

There are five minor professional leagues, each circuit having five or more teams which represent smaller cities in the United States and Canada. All of the Canadian universities and colleges, and the more important of these institutions in the United States have organized hockey teams, and in many of them hockey is ranked as a major sport.

In Canada there are over 1,200 organized amateur teams. During the past few years hockey has spread rapidly into the

northern sections of the United States. This has become possible through the more extensive use of ice in rinks prepared by artificial means in the larger arenas and auditoriums. The game being played at night in the winter, it is not dependent upon weather conditions. Furthermore, it is played at a season of the year when the great outdoor sports are not engaging the attention of sport lovers. (J. S. HA.; F. CR.)

TECHNIQUE OF THE GAME

Ordinary pleasure-skating, figure-skating and speed-skating count for little in ice hockey. The recruit must practise hours, days and months to master the "stop-turn-and-start." Ice-hockey is played in a series of short dashes,—dodging, shifting, side-stepping and even hurdling being parts of the puck-chaser's routine. The game of tag on the ice is good practice, and intensive training may be obtained in skating rounds of 10 or 20 yd. dashes, swinging the body into sharp left or right turns or even making a complete about-face at the end of the dash. The next point is to confine the skating-stride to as narrow a path of ice as possible. The professional player rushes a puck in a path as narrow as 3 ft., using a foot-over-foot stride and offering his opponents little in the way of legs, feet, stick and body to reach for. The close, choppy stride is the proper skating form to carry a player and his puck safely through an opposing team.

Many mediocre skaters have held positions in good teams through their knowledge of handling a hockey stick,—pushing the rubber puck along the ice with the 4 ft. hickory war-club, forward, sideways left to right; holding it steady with a sudden stopping or "feinting" motion and varying the whole routine with such tricky manipulations of the feet and body as completely to baffle opponents who attempt to steal the puck and thereby check the play. Years of constant practise are necessary to crown the efforts of the expert stick-handler. Professional players in the big leagues "stick-handle" the 3 in. rubber puck in a manner that is uncanny,—pushing and tossing the small rubber pellet about the ice between a maze of sticks and skates with a speed and accuracy too bewildering for the human eye to follow.

Methods of rushing, or "carrying," a puck along the ice vary. Some push the disc ahead at stick's length when the play is open; others play the puck from side to side and close to their feet at all times. Some flip the rubber against the sideboards, depending on the rebound for recovery of the disc, while others attempt to poke the puck between the opponents' feet and skate their man to regain possession of the disc while the opponents are off balance or too befuddled to hamper the play effectively. Stick-checking calls for quick thinking and clever action on the part of the checker. The poke, sweep and hook checks are effective means of stopping opposing forwards in their rush toward the goal. The body-check in hockey is the same exhibition of brute strength, superior weight and sheer roughness that is used in football and other sports.

With skating and stick-handling perfected to a point where they are combined into one mechanical operation, the player can direct his whole attention to playing the game. A good hockey player never looks at his feet, stick or puck during the progress of the play. His eyes must be focused on his opponents at all times. Once he comes into possession of the puck he has three forwards, two defence-men and a goal-tender to beat before he can register a score by shooting the rubber disc into the 4 by 6 ft. goal-net guarded by the opposing team.

Left wing, centre and right wing, commonly known as "the forward line," should practise passing the puck from one to the other across the ice, while skating at top speed, until their combination-play is perfected to a point which enables them to beat the opposing forwards, swoop in on the opposing defence, and leave the odd man in position for a shot at the net. Individual rushes by self-styled stars seldom result in tallies being marked on the scoreboard. Left and right wing players should at all times play their positions in their respective alleys and leave the centre alley or mid-ice section to the centre player. Members of the forward-line are supposed to score goals when the opportunity is presented and never at the cost of allowing the opposing forwards to break away for a two- or three-man combination

attack on the home team's net.

Defence-men, working within a 20-yd. radius of the goal-net, should never leave their goal-tender unguarded. The good defence player must hold, at all times, a position between his goal-tender and the opposing forwards who attempt to carry the puck close enough to the net for a shot that may mean a score. Defence players adopt various forms of checking the forward line attack. Some use a stick or body check or a combination of the two; others crowd the incoming forwards to the sideboards or sandwich their man between their bodies for what is known as a "hoist"—anything to spoil the forwards' shots, keep them out of shooting range of the goal-net or force them to shoot from impossible angles.

A goal-tender has 4 by 6 ft. of open net to protect and must study the shots from all angles and positions on the ice. He must cover as much of his net as possible with his body and shift his position between the posts continuously to hamper the vision of the opposing sharp-shooters. If an opposing left-winger or right-winger gets through the defence for a shot the net-guardian crowds the corner of the goal nearest to the winger, who is delivering the shot from the left-wing or right-wing "alley." When a forward skates through the defence and looms up directly in front of the net for a shot, there is little the goal-tender can do but attempt to anticipate the direction of his opponent's shot, as good forwards always shoot for the top or lower corners of the net.

(J. Fr.)

ICELAND, an island in the North Atlantic ocean (Dan. *Island*). Its extreme northerly point is touched by the Arctic Circle; it lies between 13° 22' and 24° 35' W., and between 63° 12' and 66° 33' N., and has an area of 40,437 sq. miles. Its length is 298 m. and its breadth 194 m., the shape being a rough oval, broken at the north-west, where a peninsula, diversified by a great number of fjords, projects from the main portion of the island. The total length of the coast-line is about 3,730 m., of which approximately one-third belongs to the north-western peninsula. Iceland is a plateau or tableland, built up of volcanic rocks of older and younger formation, and pierced on all sides by fjords and valleys. Compared with the tableland, the lowlands have a relatively small area, namely, one-fourteenth of the whole; but these lowlands are almost the only parts of the island which are inhabited. In consequence of the rigour of its climate, the central tableland is absolutely uninhabitable. At the outside, not more than one-fourth of the area of Iceland is inhabited; the rest consists of elevated deserts, lava streams and glaciers. The north-west peninsula is separated from the main mass of the island by the bays Húnaflói and Breiðfjörður, so that there are really two tablelands, a larger and a smaller. The isthmus which connects the two is only 4½ m. across, but has an altitude of 748 feet. The mean elevation of the north-west peninsula is 2,000 feet. The fjords and glens which cut into it are shut in by precipitous walls of basalt, which plainly shows that they have been formed by erosion through the mass of the plateau. The surface of this tableland is bare and desolate, being covered with gravel and fragments of rock. Here and there are large straggling snowfields, the largest being Glámu and Drangajökull, on the culminating points of the plateau. The only inhabited districts are the shores of the fjords, where grass grows capable of supporting sheep; but most of the population gain their livelihood by fishing.

The other and larger tableland, which constitutes the substantial part of Iceland, reaches its culminating point in the south-east, in the gigantic snowfield of Vatnajökull, which covers 3,300 sq. miles. The axis of highest elevation of Iceland stretches from north-west to south-east, from the head of Hvammsfjörður to Hornafjörður, and from this water-parting the rivers descend on both sides. The crest of the water-parting is crowned by a chain of snow-capped mountains, separated by broad patches of lower ground. They are really a chain of minor plateaux, which rise 4,500 to 6,250 ft. above sea-level and 2,000 to 3,000 ft. above the tableland itself. In the extreme east is Vatnajökull, which is separated from Tungnafellsjökull by Vonarskard (3,300 ft.). Between Tungnafellsjökull and Hofsjökull lies the broad depression of Sprengisandr (2,130 ft.). Continuing north-west, between

Hofsjökull and the next snow-capped mountain, Langjökull, lies Kjölur (2,000 ft.); and between Langjökull and Eiríksjökull, Flosaskard (2,630 ft.). To the north of the *jöklar* last mentioned there are a number of lakes, all well stocked with fish. Numerous valleys or glens penetrate into the tableland, especially on the north and east, and between them long mountain spurs, sections of the tableland which have resisted the action of erosion, thrust themselves towards the sea. Of these the most considerable is the mass crowned by Mýrdalsjökull, which stretches towards the south. The interior of the tableland consists for the most part of barren, grassless deserts, the surface being covered by gravel, loose fragments of rock, lava, driftsand, volcanic ashes and glacial detritus.

Save the lower parts of the larger glens, there are no lowlands on the north and east. The south coast is flat next the sea; but immediately underneath Vatnajökull there is a strip of gravel and sand, brought down and deposited by the glacial streams. The largest low-lying plain of Iceland, lying between Mýrdalsjökull and Reykjanes, has an area of about 1,550 sq. miles. In its lowest parts this plain barely keeps above sea-level, but it rises gradually towards the interior, terminating in a ramification of valleys. Its maximum altitude is attained at 381 ft. near Geysir. On the west of Mount Hekla this plain connects by a regular slope directly with the tableland, to the great injury of its inhabited districts, which are thus exposed to the clouds of pumice dust and driftsand that cover large areas of the interior. Nevertheless the greater part of this lowland plain produces good grass, and is relatively well inhabited. The plain is drained by three rivers—Markarfljót, Thjórsá and Oelfusá—all of large volume, and numerous smaller streams. Towards the west there exist a number of warm springs. There is another lowland plain around the head of Faxaflói, nearly 400 sq.m. in extent. As a rule the surface of this second plain is very marshy. Several dales or glens penetrate the central tableland; the eastern part of this lowland is called Borgarfjörður, the western part Mýrar.

The great bays on the west of the island (Faxaflói and Breiðfjörður), as well as the many bays on the north, which are separated from one another by rocky promontories, appear to owe their origin to subsidences of the surface; whereas the fjords of the north-west peninsula, which make excellent harbours, and those of the east coast seem to be the result chiefly of erosion.

Glaciers.—An area of 5,170 sq.m. or a little more than 13% of the total area is covered with snowfields and glaciers. This extraordinary development of ice and snow is due to the raw, moist climate, the large rainfall and the low summer temperature. The snow-line varies greatly in different parts of the island, its range being from 1,300 to 4,250 feet. It is highest on the tableland, on the north side of Vatnajökull, and lowest on the north-west peninsula, to the south of North Cape. Without exception the great *névés* of Iceland belong to the interior tableland. They consist of slightly rounded domes or billowy snowfields of vast thickness. In external appearance they bear a closer resemblance to the glaciers of the Polar regions than to those of the Alps. The largest snowfields are Vatnajökull (3,280 sq.m.), Hofsjökull (520), Langjökull (500) and Mýrdalsjökull (390). The glaciers which stream off from these snowfields are often of vast extent, e.g., the largest glacier of Vatnajökull has an area of 150 to 200 sq.m., but the greater number are small. Altogether, more than 120 glaciers are known in Iceland. It is on the south side of Vatnajökull that they descend lowest; the lower end of Breidamerkurjökull was in the year 1894 only 30 ft. above sea-level. The glaciers of the north-west peninsula also descend nearly to sea-level. The great number of streams of large volume is due to the moist climate and the abundance of glaciers, and the milky white or yellowish-brown colour of their waters (whence the common name Hvítá, white) is due to the glacial clays. The majority of them change their courses very often, and vary greatly in volume; frequently they are impetuous torrents, forming numerous waterfalls.

Iceland also possesses a great number of lakes, the largest being Thingvallavatn and Thorisvatn, each about 27 sq.m. in area. Mývatn, in the north, is well known from the natural beauty of

its surroundings. Above its surface tower a great number of volcanoes and several craters, and its waters are alive with water-fowl, a multitude of ducks of various species breeding on its islands. Mývatn fills a depression between lava streams, and has a depth of not more than $8\frac{1}{2}$ feet. The group of lakes called Fiskivötn (or Veidivötn), which lie in a desolate region to the west of Vatnajökull, consist for the most part of crater lakes. The groups of lakes which lie north-west from Langjökull occupy basins formed between ridges of glacial gravel; and in the valleys numerous lakes are found at the backs of the old moraines.

Volcanoes.—Iceland is one of the most volcanic regions of the earth; volcanic activity has gone on continuously from the formation of the island in the Tertiary period down to the present time. So far as is known, there have in historic times been eruptions from 25 volcanic vents. Altogether 107 volcanoes are known to exist in Iceland, with thousands of craters, great and small. The lava-streams which have flowed from them since the Glacial epoch now cover an area of 4,650 sq. miles. They are grouped in dense masses round the volcanoes from which they have flowed, the bulk of the lava dating from outbreaks which occurred in prehistoric times. The largest volume of lava which has issued at one outflow within historic times is the stream which came from the craters of Laki at Skaptá. This belongs to the year 1783, and covers an area of 218 sq.m., and amounts to a volume represented by a cube each of whose sides measures $7\frac{1}{2}$ miles. The largest unbroken lava-field in Iceland is Oðaðahraun (Lava of Evil Deeds), upon the tableland north from Vatnajökull (2,000 to 4,000 ft. above sea-level). It is the accretion of countless eruptions from over 20 volcanoes, and covers an area of 1,300 sq.m. (or, including all its ramifications and minor detached streams, 1,700 sq.m.), and its volume would fill a cube measuring 13.4 m. in every direction.

As regards their superficies, the lava-streams differ greatly. Sometimes they are very uneven and jagged (*apalhraun*), consisting of blocks of lava loosely flung together in the utmost confusion. The great lava-fields, however, are composed of vast

sheets of lava, ruptured and riven in divers ways (*helluhraun*). The smooth surface of the viscous billowy lava is further diversified by long twisted "ropes," curving backwards and forwards up and down the undulations. Moreover, there are gigantic fissures, running for several miles, caused by subsidences of the underlying sections. The best-known fissure of this character is Almannagjá at Thingvellir. On the occasion of outbreaks the fine ashes are scattered over a large portion of the island, and sometimes carried far across the Atlantic. After the eruption of Katla in 1625 the ashes were blown as far as Bergen in Norway, and when Askja was in eruption in 1875 a rain of ashes fell on the west coast of Norway 11 hours 40 minutes, and at Stockholm 15 hours, afterwards. The volcanic ash frequently proves extremely harmful, destroying the pastures so that the sheep and cattle die of hunger and disease. The outbreak of Laki in 1783 occasioned the loss of 11,500 cattle, 28,000 horses and 190,500 sheep—that is to say, 53% of the cattle in the island, 77% of the horses and 82% of the sheep. After that the island was visited by a famine, which destroyed 9,500 people, or one-fifth of the total population.

The Icelandic volcanoes may be divided into three classes: (1) cone-shaped, like Vesuvius, built up of alternate layers of ashes, scoriae and lava; (2) cupola-shaped, with an easy slope and a vast crater opening at the top—these shield-shaped cupolas are composed entirely of layers of lava, and their inclination is seldom steeper than 7° – 8° ; (3) chains of craters running close alongside a fissure in the ground. For the most part the individual craters are low, generally not exceeding 300 to 500 feet. These crater chains are very common and often very long. The chain of Laki, which was formed in 1783, extends 20 m., and embraces about 100 separate craters. Sometimes, however, the lava-streams are vomited straight out of gigantic fissures in the earth without any crater being formed. Many of the Icelandic volcanoes during their periods of quiescence are covered with snow and ice. Then when an outbreak occurs the snow and ice melt, and in that way they sometimes give rise to serious catastrophes (*jökulhlaup*), through large areas being suddenly inundated by great floods of

water, which bear masses of ice floating on the surface. Katla caused very serious destruction in this way by converting several cultivated districts into barren wastes. In the same way in the year 1362 Oeraefajökull, the loftiest mountain in Iceland (6,424 ft.), swept 40 farms, together with their inhabitants and live stock, bodily into the ocean. The best-known volcano is Hekla (5,108 ft.), which was in eruption 18 times within the historic period down to 1845. Katla during the same period was active 13 times down to 1860. The largest volcano is Askja, situated in the middle of the lava-field of Oðaðahraun. Its crater measures 34 sq.m. in area. At Mývatn there are several volcanoes, which were particularly active in the years 1724-30. On several occasions there have been volcanic outbreaks under the sea outside the peninsula of Reykjanes, islands appearing and afterwards disappearing again. The crater chain of Laki has only been in eruption once in historic times, namely, the violent and disastrous outbreak of 1783. Iceland, however, possesses no constantly active volcano. There are often long intervals between the successive outbreaks, and many of the volcanoes (and this is especially true of the chains of craters) have only vented themselves in a solitary outburst.

Earthquakes are frequent, especially in the districts which are peculiarly volcanic. Historical evidence goes to show that they are closely associated with three naturally defined regions: (1) the region between Skjálfandi and Axarfjörðr in the north, where violent earth tremblings are extremely common; (2) at Faxaflói, where minor vibrations are frequent; (3) the southern lowlands, between Reykjanes and Mýrdalsjökull, have frequently been devastated by violent earthquake shocks, with great loss of property and life, e.g., on Aug. 14-16, 1784, when 92 farmsteads were totally destroyed, and 372 farmsteads and 11 churches were seriously damaged; and again in Aug. and Sept. 1896, when another terrible earthquake destroyed 161 farmsteads and damaged 155 others. Hot springs are found in every part of Iceland, both singly and in groups; they are particularly numerous in the western portion of the southern lowlands, where amongst others is the famous Geyser (*q.v.*). Sulphur springs and boiling mud lakes are also general in the volcanic districts; and in places there are carbonic acid springs, these more especially on the peninsula of Snaefellsnes, north of Faxaflói.

Geology.—Iceland is built up almost entirely of volcanic rocks, none of them older, however, than the middle of the Tertiary period. The earlier flows were probably contemporaneous with those of Greenland, the Faeroes, the western islands of Scotland and the north-east of Ireland. The principal varieties are basalt and palagonitic breccias, the former covering two-thirds of the entire area, the latter the remaining one-third. Compared with these two systems, all other formations have an insignificant development. The palagonitic breccias, which stretch in an irregular belt across the island, are younger than the basalt. In the north-west, north and east the coasts are formed of basalt, and rise in steep, gloomy walls of rock to altitudes of 3,000 ft. and more above sea-level. Deposits of clay, with remains of plants of the Tertiary period, lignite and tree-trunks pressed flat, which the Icelanders call *surtarbrandur*, occur in places in the heart of the basalt formation. These fossiliferous strata are developed in greatest thickness in the north-west peninsula. Indeed, in some few places well-marked impressions of leaves and fruit have been discovered, proving that in Tertiary times Iceland possessed extensive forests, and its annual mean temperature must have been at least 48° F, whereas the present mean is 35.6°. The palagonitic breccias, which attain their greatest development in the south of the island and on the tableland, consist of reddish, brown or yellowish rocks, tuffs and breccias, belonging to several different groups or divisions, the youngest of which seems to be of a date subsequent to the Glacial epoch.

All over Iceland, in both the basalt and breccia formations, there occur small intrusive beds and dikes of liparite, and as this rock is of a lighter colour than the basalt, it is visible from a distance. In the south-east of the island, in the parish of Lón, there exist a few mountains of gabbro, a rock which does not occur in any other part of Iceland. Near Húsavík in the north there have

been found marine deposits containing a number of marine shells; they belong to the Red Crag division of the Pliocene. In the middle of Iceland, where the geological foundation is tuff and breccias, large areas are buried under ancient outflows of lava, which bear evidences of glacial scratching. These lava streams, which are of a doleritic character, flowed before the Glacial age, or during its continuance, out of lava cones with gigantic crater openings, such as may be seen at the present day. During the Glacial epoch the whole of Iceland was covered by a vast sheet of inland ice, except for a few small isolated peaks rising along its outer margins. This ice-cap had on the tableland a thickness of 2,300 to 2,600 feet. Rocks scored by glacial ice and showing plain indications of striation, together with thousands of erratic blocks, are found scattered all over Iceland. Signs of elevation subsequent to the Glacial epoch are common all round the island, especially on the north-west peninsula. There are found strikingly developed marine terraces of gravel, shore lines and surf beaches marked on the solid rock. In several places there are traces of shells; and sometimes skeletal remains of whales and walruses, as well as ancient driftwood, have been discovered at distances from the present coast. The ancient shore-lines occur at two different altitudes. Along the higher, 230 to 260 ft. above the existing sea-level, shells have been found which are characteristic of high Arctic latitudes and no longer exist in Iceland; whereas on the lower shore-line, 100 to 130 ft., the shells belong to species which occur amongst the coast fauna of the present day.

The geysers and other hot springs are due to the same causes as the active volcanoes, and the earthquakes are probably manifestations of the same forces. A feature of special interest to geologists in the present conditions of the island is the great power of the wind both as a transporting and denuding agent. The rock sculpture is often very similar to that of a tropical desert. (See Th. Thoroddsen, "Explorations in Iceland during the years 1881-1898," *Geographical Journal*, vol. xiii. [1899], pp. 251-274, 480-513, with map.)

Climate.—Considering its high latitude and situation, Iceland has a relatively mild climate. The meteorological conditions vary greatly, however, in different parts of the island. In the south and east the weather is generally changeable, stormy and moist; whilst on the north the rainfall is less. The climate of the interior tableland approximates to the Continental type and is often extremely cold. The mean annual temperature is 37.2° F in Stykkishólmr. The range is great not only from year to year, but also from month to month. For instance, at Stykkishólmr the highest annual mean for March was 39.7°, and the lowest 8°, during a period of 38 years. Iceland lies contiguous to that part of the north Atlantic in which the shifting areas of low pressure prevail, so that storms are frequent and the barometer is seldom firm. The barometric pressure at sea-level in the south-west of Iceland during the period 1878-1900 varied between 30.8 and 27.1 inches.

The climate of the coasts is relatively mild in summer, but cold in winter. The winter means of the north and east coasts average 31.7° and 31.3° F respectively; the summer means, 42.8° and 44.6°; and the means of the year, 33.1° and 35.6°. The winter means of the south and west coasts average 32° and 31.7° respectively; the summer means, 48.2° and 50°; the annual means, 37.4° and 39.2°. The rainfall on the south and east coasts is considerable, e.g., at Vestmannaeyjar, 49.4 in. in the year. On the west coast it is less, e.g., 24.3 in. at Stykkishólmr; but least of all on the north coast, being only 14.6 in. on the island of Grimsey, which lies off that coast. Mist is commonly prevalent on the east coast; at Berufjörðr there is mist on no fewer than 212 days in the year. The south and west coasts are washed by the Gulf stream, and the north coast by an Arctic current, which frequently brings with it a quantity of drift-ice, and thus exercises a considerable effect upon the climate of the island; sometimes it blocks the north coast in the summer months. On the whole, during the 19th century, the north coast was free from ice on an average of one year in every four or five. The clearness of the atmosphere has been frequently remarked. Thunderstorms occur mostly in winter.

Flora.—The vegetation presents the characteristics of an Arctic European type, and is tolerably uniform throughout the island, the differences even on the tableland being slight. At present 435 species of phanerogams and vascular cryptogams are known; the lower orders have been little investigated. The grasses are of the greatest importance to the inhabitants, for upon them they are dependent for the keep of their live stock. Heather covers large tracts, and also affords pasture for sheep. The development of forest trees is insignificant. Birch woods exist in a good many places, especially in the warmer valleys; but the trees are very short, scarcely attaining more than 3 to 10 ft. in height. In a few places, however, they reach 13 to 20 ft. and occasionally more. A few mountain ash or rowan trees (*Sorbus aucuparia*) are found singly here and there, and attain to 30 ft. in height. Willows are also pretty general, the highest in growth being *Salix phylicifolia*, 7 to 10 feet. The wild flora of Iceland is small and delicate, with bright bloom, the heaths being especially admired. Wild crowberries and bilberries are the only fruit found in the island.

Fauna.—The Icelandic fauna is of a sub-Arctic type. But while the species are few, the individuals are often numerous. The land mammals are very poorly represented; and it is doubtful whether any species is indigenous. The polar bear is an occasional visitant, being brought to the coast by the Greenland drift-ice. Foxes are common, both the white and the blue occurring; mice and the brown rat have been introduced, though one variety of mouse is possibly indigenous. Reindeer were introduced in 1770, and without the aid of these strong, heavily built animals, many portions of the country could scarcely be permanently inhabited; these reindeer can maintain a speed of nine to ten miles an hour for long periods at a time, and draw a weight of over 200 lbs.

The marine mammalia are numerous. The walrus is now seldom seen, although in prehistoric times it was common. There are numerous species of seals; and the seas abound in whales. Of birds there are over 100 species, more than one-half being aquatic. In the interior the whistling swan is common, and numerous varieties of ducks are found in the lakes. The eider duck, which breeds on the islands of Breiðfjörður, is a source of livelihood to the inhabitants, as are also the many kinds of sea-fowl which breed on the sea-cliffs. Iceland possesses neither reptiles nor batrachians. The fish fauna is abundant in individuals, some 68 species being found off the coasts. The cod fisheries are amongst the most important in the world. Large quantities of herring, plaice and halibut are also taken. Many of the rivers abound in salmon, and trout are plentiful in the lakes and streams.

Population and Towns.—With a population of about 100,000 (in 1925) Iceland is the most sparsely populated country in Europe. Remembering that almost four-fifths of the island are uninhabited and almost uninhabitable, the distribution of population gives an average of something less than one per square kilometre. In the earlier days of its settlement Iceland suffered from disasters and visitation of plagues, which greatly decreased the number of its population. The Black Death, which ravaged the country from 1402-04, is supposed to have killed off no less than two-thirds of the inhabitants. The increase of population during the 19th century was counterbalanced by the number of Icelanders who emigrated to America, chiefly to Manitoba and Saskatchewan. The highest figures of emigration were reached in 1887 when about 2,000 persons emigrated. In the present century an average of about 200 per year emigrated until 1915, when emigration practically stopped. The population of Iceland consists almost exclusively of Icelanders. The census of 1920 shows only 0.7% were born out of Iceland. The largest town is Reykjavík, on the Faxaflói, with about 22,000 inhabitants, the capital of the island and the seat of Government. Here also are the Icelandic university and many of the principal schools of the country, together with the cathedral, whose marble font was made by Albert Thorvaldsen, whose father was an Icelandic. Other towns include, Akureyri (pop. 2,906), Vestmannaeyjar (pop. 2,841), Hafnarfjörður (2,692), Ísafjörður (2,158).

Industries.—The classification of the population according to occupations is shown in the following summary based upon the census of 1920:

Public service, art and science	3,417	3.6%
Farming	40,614	42.9%
Fisheries	17,947	18.9%
Handicraft and industry	10,697	11.3%
Commerce and communications	11,539	12.2%
Servants	6,436	6.8%
Pensioners and "retired" men	1,866	2.0%
Receiving poor relief	1,482	1.6%
Profession not stated	692	0.7%
	94,690	100.00%

Though farming is still the chief occupation of the population yet formerly it was so in a much higher degree. In 1880 73.2% were engaged in farming compared with 42.9% in 1920, while there has been a material rise in the numbers engaged in fisheries, industry, handicraft, communications and commerce. Farmers are largely occupied with cattle-breeding, and more particularly sheep-breeding. Grain is not cultivated in Iceland, all bread-stuffs being imported. An attempt to grow barley proved to be an economic failure. Considerable progress has been made in modern times in the cultivation of turnips and potatoes. While fruit trees do not thrive, black and red currants and rhubarb grow excellently. In nearly every district a small agricultural association is found; there are also four agricultural schools and one agricultural society in Iceland.

Fisheries now furnish employment to about one-fifth of the population. There has been a marked development of the fishing fleet during the last 25 years, due solely to the increased employment of trawlers and large and small motor boats. In 1922 the trawler fleet consisted of 31 ships, with an average measurement of some 300 gross reg. tons each, while the whole motor ship fleet had a total of 3,938 tons (gross reg.).

This development of the fisheries has greatly influenced the distribution of the population, and has been the cause of the migration of people from rural to coastal districts. Practically the whole fishing fleet is employed in fishing cod and cod-like species, and the winter fishing season (the first four to five months of the year) off the south coast of Iceland yields about three-fifths of the total catch of the year. In summer the waters are visited by a great number of fishing-boats from French ports, the Faeroes and Norway, and by steam-trawlers from Britain. Inspection of fishing grounds is at present carried out by Danish patrol boats, and the maritime jurisdiction of Iceland, as far as the fisheries are concerned, is fixed by a treaty made between Denmark and Great Britain on March 28, 1903. Many public measures have been taken for the encouragement of salt-water fisheries, the chief being an annual grant from the budget, the Fishing Fund, which grants loans for the purchase of vessels and fishing gear and which derives its increased capital from the fines for illegal fishing and the sale of forfeited gear, and the Sea-territorial Fund, which derives its capital from the same source and is concerned with the provision of protective patrol boats. The Icelandic Association for the Promotion of the Fishing Trade was established in 1911, has 41 local branches and a membership of 1,500 in 1924; it issues a monthly and gives short courses in navigation and in motor repairs. On the initiative of the State there is now a marine mutual insurance company and two special schools for sailors and fishermen, one for marine engineers and one in navigation. The total export of fish in 1923 was 59,464 tons, to the value of 37.2 million kroner.

Commerce.—In 1902 imports were valued at £596,193 and exports at £511,083. In 1923 imports were valued at £2,794,151 and exports at £3,194,283. Trade is almost entirely with Denmark, the United Kingdom, and Norway and Sweden, in this order according to value. The principal native products exported are live sheep, horses, salt meat, wool and hides, to which must be added the fish products—cod, train-oil, herring and salmon—eiderdown and woollen wares. The spinning, weaving and knitting of wool is a widespread industry, and the native tweed (*vaðmal*) is the principal material for the clothing of the inhabitants. The imports consist principally of cereals and flour, coffee, sugar, ale, wines and spirits, tobacco, manufactured wares, iron and metal wares, timber, salt, coal, etc. The money, weights

and measures in use are the same as in Denmark. The Islands Bank in Reykjavik (1904) is authorized to issue bank-notes up to £133,900 in total value. This was greatly increased during the World War, and a special committee has now been appointed to make proposals regarding the definite fixing of the note issue.

Communications.—All land journeys are made on horse-back, and in the remoter parts all goods have to be transported by the same means. Throughout the greater part of the island there exist no proper roads, even in the inhabited districts, but only bridle-paths, and in the uninhabited districts not even these. Nevertheless, under the Roads Act, much has been done to improve such paths as there are, and several miles of driving roads have been made, more particularly in the south. Since 1888 many bridges have been built; previous to that year there were none. The larger rivers have been spanned by iron swing-bridges, and the Blanda is crossed by a fixed iron bridge. Postal connection is maintained with Denmark by steamers, which sail from Copenhagen and call at Leith. Besides, steamers go round the island, touching at nearly every port. Since motor cars were introduced in 1913 their number has increased until, in 1925, 400 had been registered. No railways exist, but a preliminary survey has been made for a line from Reykjavik to the southern lowlands. A wireless telegraph station was opened in 1917. Iceland controls its own steamship company with six mail steamers.

Religion.—The Icelanders are Lutherans. The island forms one bishopric, with its see at Reykjavik, and there are two vice-bishops, one for each of the two dioceses into which the island was formerly divided. There are 20 deaneries, each with a district council, and 142 parishes administered by a parish council. Candidates for the priesthood must now, as a rule, have taken a theological degree at the University of Iceland, and clergymen are chosen by a secret voting on the part of such of the parishioners who are of full age (21 years) and of blameless reputation.

The Icelandic Church has always been liberal in her views, and many adherents to the new theology and the doctrines of spiritualism are found among the younger clergy.

Health.—In 1923 the birth rate was 26.5 per 1,000, and the death rate was 12.5 per 1,000, the latter showing a marked improvement on pre-war figures. This improvement is due to greater cleanliness, better housing and nourishment, and the increase in the number of doctors. There is a modern asylum for leprosy near Reykjavik, and the building of a large State hospital at Reykjavik was commenced in 1925. There is also a mental hospital and a sanatorium, as well as a number of minor infirmaries. The chief surgeon (national physician), who resides at Reykjavik, is in charge of the general sanitary affairs of the island, and has superintendence over the doctors and the medical school.

Government.—According to the Constitution granted to Iceland in 1874, and amended by the Icelandic Parliament Act of 1903 and 1918, the king of Denmark shares the legislative power with the Althing, an assembly of 42 popularly elected members, 36 of whom are elected by the constituencies for a period of four years. Six members are chosen by the whole electorate, according to proportional representation, for a period of eight years. These last six form the upper house and the remainder the lower house, but upon occasions the two houses work together in a united Althing.

The Althing now meets every year, but formerly sat only in alternate years.

Iceland has its own prime minister, who must be an Icelander and reside in Reykjavik. He is responsible to the king and to the Althing, and is aided in the work of administration by a secretary of State and three chiefs of departmental bureaux. For convenience he has a sub-office in Copenhagen, for the purpose of laying the measures approved by the Althing before the king, for his sanction and signature.

The island is divided into 16 districts (*sýslur*) each of which is administered by a district magistrate (*sýslumenn*), and seven towns administered by town magistrates. These magistrates act as tax-gatherers, notaries public and judges of first instance. The counties are divided into 169 *hreppur* (rapes) poor-law districts,

and in each *hreppur* the magistrate has an assistant, called *hreppstjóri*.

From the magistrates' courts appeals lie to the superior court at Reykjavik, consisting of three judges, and appeals may further be taken in all criminal and in most civil cases to the supreme court at Copenhagen.

In Feb. 1928 the Althing agreed that it was desirable to cancel the present treaty of personal unity with Denmark, thereby obtaining complete independence.

Education.—There is compulsory elementary education between the ages of 10 and 14 years. In towns, trading stations and some rural districts children receive instruction at "stationary" schools for six months of the year; where this is impossible, "movable" schools have been provided, in which each child receives instruction for at least two months of the year. In various parts of the country there are "schools for youths" providing courses of instruction of secondary school nature. In Reykjavik there is a "Mentaskóli" (State school) and the final examination here entitles those who pass it to matriculation at the university. There are also a number of technical schools, most of which provide a general, as well as a professional education, such as training college for elementary teachers, theological school, nautical school, agricultural schools, schools for marine engineers, and evening technical schools for apprentices in various towns. There is a national library at the capital containing some 116,000 printed volumes and 7,500 mss., and almost every district has a public library.

There is a daily newspaper, several weeklies and a number of periodical publications (monthlies and quarterlies). Among the learned societies are the Icelandic Literary Society, the Society of the Friends of the People and the Archaeological Society of Reykjavik.

HISTORY

The discovery of Iceland by the Scandinavians, c. 850 (it had long been inhabited by a small colony of Irish Culdees), led in sixty years, to the establishment of some 4,000 homesteads. In this immigration three distinct streams can be traced. (1) About 870-890 four great noblemen from Norway, settled with their dependants in the south-west. (2) In 890-900 there came from the Western islands Queen Aud, widow of Olaf the White, king of Dublin, preceded and followed by a number of her kinsmen and relations (many like herself being Christians), who settled the best land in the west, north-west and north, and founded families who long swayed its destinies. There also came from the Western islands a fellowship of vikings seeking a free home in the north. They had fled from Harald Haarfager's rule and colonized the west in the viking times. (3) In 900-930 a few more incomers direct from Norway completed the settlement of the south, north-east and south-east. Among the immigrants there was no small proportion of Irish blood. In 1100 there were 4,500 franklins,

i.e., about 50,000 souls.

The unit of Icelandic politics was the homestead with its franklin-owner (*buendi*), its primal organization the hundred-moot (*thing*), its tie the *goðorð* (godar) or chieftainship. The chief who had led a band of kinsmen and dependants to the new land, naturally became their leader, presiding as priest at the feasts and sacrifices, acting as speaker of their moot, and as their representative towards the neighbouring chiefs. He was not a feudal lord, for any franklin could change his *goðorð* when he would, and the rights of "judgment by peers" were in full use; moreover, the office could be bequeathed, sold, divided or pledged by the possessor; still the *goði* had considerable power as long as the commonwealth lasted.

Disputes and uncertainty about the law, brought about the *Constitution of Úlfiot* (c. 930), which appointed a central moot for the whole island, the Althing; the *Reforms of Thord Gellir* (964), settling a fixed number of moots and chieftaincies, dividing the island into four quarters, to each of which a head-court, the "quarter-court," was assigned; and the *Innovations of Skapti* (ascribed in the saga to Nial) the *Law-Speaker* (d. 1030), who set up a "fifth court" as the ultimate tribunal in criminal matters. But here constitutional growth ceased: the law-making body made few and unimportant modifications of custom; the courts were too weak for the chiefs, who defied them; the speaker's power was not sufficiently supported; even the ecclesiastical innovations, while they secured peace for a time, provoked in the end the struggles which put an end to the commonwealth.

Union with Norway.—Christianity was introduced c. 1000 from Norway. Tithes were established in 1096, and an ecclesiastical code made c. 1125. The first disputes about the jurisdiction of the clergy were moved by Gudmund in the 13th century, bringing on a civil war, while the questions of patronage and rights over glebe and mortmainland occupied Bishop Arni and his adversaries fifty years afterwards, when the land was under Norwegian viceroys and Norwegian law. For the civil wars broke down the great houses who had monopolized the chieftaincies; and after violent struggles the submission of the island to Norway quarter after quarter took place in 1262–64, under Gizur's auspices, and the old Common Law was replaced by the New Norse Code "Ironside" in 1271.

The political life and law of the old days is abundantly illustrated in the sagas (especially *Eyrbyggja*, *Hensa-Thori*, *Reykdaela*, *Hrafnkell* and *Njala*), the two collections of law-scrolls (*Codex Regius*, c. 1235, and *Stadarhol's Book*, c. 1271), the *Libellus*, the *Liberfragments* and the *Landnamabok* of Ari and the *Diplomatarium*. (See K. Maurer *Beiträge zur Rechtsgeschichte des Germanischen Nordens* [Munich 1852]; *Island von seiner ersten Entdeckung bis zum Untergang des Freistaats* [Munich 1874].)

The mediaeval Icelandic church had two bishoprics, Skalholt (1056) and Holar (1106), and about 175 parishes. They belonged to the metropolitan see of Bremen, then to Lund, lastly to Nidaros, 1237. There were several religious foundations, Benedictine and Augustinian, dating from the 12th to 15th centuries. The bishops, elected by the people at the Althing till 1237, enjoyed considerable power; two, Thorlak of Skalholt and John of Holar, were publicly voted saints at the Althing. For ecclesiastical history see "*Biskupasögur*" in *Origines Islandicae* Bk. 1 (ed. and trans. G. Vigfusson and F. York Powell 1905).

Iceland was pastoral, depending upon herds for subsistence, for, though rye and other grain would grow in favoured localities, the hay, self-sown, was the only regular crop. In some districts the fisheries and fowling were also of importance. Outdoor occupations—fishing, shepherding, fowling, hay-making and fuel-gathering—occupied the summer; while indoor business—weaving, tool-making, etc.—filled up the long winter. The year was broken by the spring feasts and moots, the great Althing meeting at midsummer, the marriage and arval gatherings after the summer, and the long yule feasts at midwinter. There were but two degrees of men, free and unfree, though only the franklins had any political power; and, from the nature of the life, social intercourse was unrestrained; *goði* and thrall lived the same lives, ate the same food, spoke the same tongue, and differed little in clothing or

habits. The thrall had a house of his own and was rather villain or serf than slave, having rights and a legal price by law. During the heathen days many great chiefs passed part of their lives in Norway at the king's court, but after the establishment of Christianity in Iceland they kept more at home, visiting the continent, however, for purposes of state, suits with clergy, etc. Trade was from the first almost entirely in foreign (Norse) hands.

Life in the commonwealth was turbulent and anarchic, but free and varied; it produced men of mark, and fostered bravery, adventure and progress. But on the union with Norway all this ceased, and there was left but a low dead level of poor peasant proprietors careless of all save how to live by as little labour as possible, and pay as few taxes as they could to their foreign rulers. The island received a foreign governor (*Earl*, *Hirdstjóri* or *Stiptamismadr* as he was successively called), and was parcelled out into counties (*sýslur*), administered by sheriffs (*sýslumadr*) appointed by the king. A royal court took the place of the Althing courts; the local business was carried out by the (*hreppstjóri*) bailiff, a subordinate of the sheriff; and the *goðorð* things, quarter-courts, trial by jury, etc., were swept away by these innovations. The power of the crown was increased by the confiscation of the great Sturlung estates, which were underleased to farmers, while the early falling off of the Norse trade threatened to deprive the island of the means of existence; for the great epidemics and eruptions of the 14th century had gravely attacked its pastoral wealth and ruined much of its pasture and fishery.

Union with Denmark.—The union of the Three Crowns transferred the practical rule of Iceland to Denmark in 1280, and the old Treaty of Union, by which the island had reserved its essential rights, was disregarded by the absolute Danish monarchs. During the whole of the 15th century their trade with England, exporting sulphur, eiderdown, wool and salt stock-fish, and importing as before wood, iron, honey, wine, grain and flax goods, was their only link with the outer world. This period of Iceland's existence is eventless: she had got peace but with few of its blessings; even shepherding and agriculture sank to a lower stage; wagons, ploughs and carts went out of use; architecture in timber became a lost art, and the fine carved and painted halls of the heathen days were replaced by turf-walled barns half sunk in the earth; the large decked luggers of the old days gave way to small undecked fishing-boats.

The Reformation in Iceland wakened men's minds, but it left their circumstances little changed. When it was accomplished, the little knot of able men who came to the front did much in preserving the records of the past, while Odd and Hallgrim exhibit the noblest impulses of their time. The Hanse trade replaced the English for the worse; and the Danish monopoly which succeeded it when the Danish kings began to act again with vigour was still less profitable. The subservient Lutheran clergy became the most powerful class in the island, while the system of under-leasing at rackrent and short lease with unsecured tenant right extended over at least a quarter of the better land.

A new plague, that of the English, Gascon and Algerine pirates, at the close of the 16th century and opening of the 17th, caused widespread panic and some devastation in 1579, 1613–16 and 1627. But the 18th century is the most gloomy in Iceland's annals. Smallpox, famine, sheep disease and the eruptions of 1765 and 1783 follow each other in terrible succession. Against such visitations, which reduced the population by about a fourth, little could be done. The few literary men, whose work was done and whose books were published abroad, were only concerned with the past, and Jon Vidalin is the one man of mark, beside Eggert Olafsson, who worked and wrote for his own generation.

Gradually the ideas which were agitating Europe spread through Scandinavia into Iceland, and its claims were more respectfully listened to. The continental system, which, by its leading to the blockade of Denmark, threatened to starve Iceland, was neutralized by special action of the British government. Trade and fishery grew a little brisker, and at length the turn came.

The rationalistic movement, headed by Magnus Stephenson, a patriotic, narrow-minded lawyer, did little good as far as church reform went, but was accompanied by a more successful effort to

educate the people. Newspapers and periodicals were published, and the very stir which the ecclesiastical disputes encouraged did good. When free trade came, and when the free constitution of Denmark had produced its legitimate effects, the endeavours of a few patriots such as Jon Sigurdsson were able to push on the next generation a step further. Questions of a modern political complexion arose; the cattle export controversy and the great home rule struggle began. After thirty years' agitation home rule was conceded in 1874 and in 1918 Iceland was recognized as a separate kingdom, with unlimited sovereignty, in personal union with Denmark. According to the Act of Union there are no real joint affairs; Denmark, however, provisionally till 1940, takes charge of the foreign affairs of Iceland as its mandatory. For the same period Danish and Icelandic citizens, residing in either State, enjoy in every respect equal rights. Since 1915 Iceland has had its own merchant flag; since 1918 its own national arms. Abroad Danish legations act on behalf of both Denmark and Iceland. Iceland has had a legation in Denmark, and Denmark a legation in Iceland since 1921; other states are represented in Iceland by consulates.

ICELANDIC LANGUAGE. Closely akin to Norwegian, Old Icelandic was spoken in Iceland and in Greenland. A voluminous literature dates from the first half of the 12th century, written in the Latin alphabet and adapted to the special requirements of this language. No traces are found of any older runic literature. The runic monuments (about 45) are almost worthless from a philological point of view. The oldest, which date from the early 13th century, are later than the oldest manuscripts in the Latin alphabet.

Form of the Language.—The oldest form of the Icelandic language is preserved in the later manuscripts of the 13th century, which contain poems by the oldest Icelandic poets, the metrical form having been the means of preserving the ancient language.

Two of the oldest and most essential characteristics of Icelandic as opposed to Norwegian are the more complete vowel assimilation (*þionasto*, *þionasto*); and the retention of initial *h* before *r* (*hreinlega*, *ræinlega*), *l* and *n*. Other differences, some of which occur at this period, others a little later, are—in Icel., lengthening of *a*, *o*, *u* before *lj*, *lg*, *lk*, *lm* and *lp* (as Icel. *hálfr*, Norw. and oldest Icel. *halfr*, half); later still, also of *a*, *i*, *u* and *y* before *ng* and *nk*; Icel. *é* and *ey* for older *ø* and *øy* (as in Icel. *dæma*, *heyra*, Norw. and oldest Icel. *døma*, to deem, *høyra*, to hear); Icel. termination of 2nd plur. of verbs in *ð* (*þ*) or *t*, but Norw. often in *-r* (as Icel. *takið*, *-t*, Norw. *takir*, you take). At the middle of the 13th century the written language undergoes material changes. Thus in unaccented syllables *i* now appears for older *e*, and *u* (at first only when followed by one or more consonants belonging to the same syllable) for *o*; the passive ends in *-z* for *-sk*. Other differences from Norwegian are now completely established. With the beginning of the 14th century there appear several new linguistic phenomena: a *u* is inserted between final *r* and a preceding consonant (as in *ríkur*, mighty); *q* (pronounced as an open *o*) passes into *ö* (the character *ö* was not introduced till the 16th century), or before *ng*, *nk* into *au* (as *lönq fiöll*, pronounced *laung fiöll*); *e* before *ng*, *nk* passes into *ei*; a little later *é* passes into *ie*, and the passive changes its termination from *-z*, oldest *-sk*, into *zt* (or *zst*) (as in *kallast*, to be called). The post-classical period of Old Icelandic (1350–1530) already shows marked differences that are characteristic of Modern Icelandic; *kn* has, except in the northern dialects, passed into *hn*, as *knútr*, knot; as early as the 15th century we find *ddl* for *ll* and *rl* (as *falla*, pronounced *faddla*, to fall), *ddn* for *nn* and *rn* (as *horn*, pron. *hoddn*, horn), and a little later the passive ends in *-st*, e.g., *kallast*, to be called.

Dialects.—Dialectal differences do not occur to any great extent in the Old Icelandic literary language. To what extent the language of Greenland differed from that of Iceland we cannot judge from the few runic monuments which have come down to us from that colony.

Modern Icelandic.—The speech of modern Iceland has developed quite naturally from the ancient tongue. It bears a

strong resemblance to the modern Scandinavian tongues, especially Norwegian. With the tendency in recent years toward uniformity in speech among the Danes, Swedes and Norwegians, this *rapprochement* has become more marked and a fluent speaker of what is sometimes called Dano-Norwegian would have little difficulty in speaking and understanding modern Icelandic. The semi-vowels are modified in certain well-defined ways (Icelandic *liuom* is Norw. *lifom*), and vocalic assimilation is still strong in Icelandic, whereas it tends to become lost in Norwegian. There is increasing vigour in the modern Icelandic as evidenced by the steady growth of publications. (See ICELANDIC LITERATURE.)

ICELANDIC LITERATURE. Iceland has always borne a high renown for song, but has never produced a poet of the highest order, the qualities which in other lands were most sought for and admired in poetry being in Iceland lavished on the saga, a prose epic, while Icelandic poetry is to be rated very high for the one quality which its authors have ever aimed at—melody of sound. To these generalizations there are few exceptions, though Icelandic literature includes a group of poems which possess qualities of high imagination, deep pathos, fresh love of nature, passionate dramatic power, and noble simplicity of language which Icelandic poetry lacks. The solution is that these poems do not belong to Iceland at all. They are the poetry of the "Western islands."

The Western Isles School.—It was from among the Scandinavian colonists of the British coasts that in the first generations coming after the colonization of Iceland a magnificent school of poetry arose, to which we owe works that for power and beauty can be paralleled in no Teutonic language till centuries after their date. To this school, which is totally distinct from the Icelandic, and which ran its own course and perished before the 13th century, the following works belong. Of their authors we have scarcely a name or two; their dates can be rarely exactly fixed, but they lie between the beginning of the 9th and the end of the 10th centuries. The poems are classified into groups:—

(a) The *Helgi* trilogy (last third lost save a few verses, but preserved in prose in *Hromund Gripsson's Saga*), the *Raising of Anganty* and *Death of Hialmar* (in *Hervarar Saga*), the fragments of a *Volsung Lay* (*Völsungakviða*) (part interpolated in earlier poems, part underlying the prose in *Völsunga Saga*), all by one poet, to whom Dr. Vigfússon would also ascribe *Völuspá*, *Vegtamskviða*, *Þrymskviða*, *Gróttu Song* and *Völundarkviða*.

(b) The Dramatic Poems:—*Flyting of Loki*, the *För Skírnis*, the *Hárbarðsljóð* and several fragments, all one man's work, to whose school belong, probably, the *Lay* underlying the story of Ivar's death in *Skjöldunga Saga*.

(c) The Didactic Poetry:—*Grímnismál*, *Vafþrúðnismál*, *Alvíssmál*, etc.

(d) The Genealogical and Mythological Poems:—*Hyndluljóð*, written for one of the Haurda-Kari family, so famous in the Orkneys; *Ynglingatal* and *Haustlög*, by Thiodolf of Hvin; *Ríg's Thul*, etc.

(e) The Dirges and Battle Songs—such as that on Hafur-firth Battle *Hrafnsmál*, by Thiodolf of Hvin or Thorbjörn Hornklofi, shortly after 870; Eirik's Dirge (*Eiríksmál*) between 950 and 969; the *Dart-Lay on Clontarf Battle* (1014); *Bjarka-mál* (fragments of which we have, and paraphrase of more is found in *Hrólfr Kraki's Saga* and in Saxo).

There are also fragments of poems in *Half's Saga*, *Asmund Kappa-Bana's Saga*, in the Latin verses of Saxo, and the Shield Lays (*Ragnarsdrápa*) by Bragi, etc., of this school, which closes with the *Sun-Song*, a powerful Christian Dantesque poem, recalling some of the early compositions of the Irish Church, and with the 12th century *Lay of Ragnar*, *Lay of Starkad*, *The Proverb Song* (*Hávamál*) and *Krákumál*, to which we may add those singular Gloss-poems, the *Pulur*, which also belong to the Western Isles.

To Greenland, Iceland's farthest colony, founded in the 10th century, we owe the two *Lays of Atli*, and probably *Hymiskviða*, which, though of a weirder, harsher cast, yet belong to the Western isles school and not to Iceland.

In form all these poems belong to two or three classes:—*kviða*, an epic "cantilena"; *tal*, a genealogical poem; *drápa*, songs of praise, etc., written in modifications of the old Teutonic metre which we know in Beowulf; *galdr* and *lokk*, spell and charm songs in a more lyric measure; and *mál*, a dialogue poem, and *ljód*, a lay, in elegiac measure suited to the subject.

The characteristics of this Western school are no doubt the result of the contact of Scandinavian colonists of the viking-tide, living lives of the wildest adventure, with an imaginative and civilized race, that exercised upon them a very strong and lasting influence (the effects of which were also felt in Iceland, but in a different way). The frequent intermarriages which mingled the best families of either race are sufficient proof of the close communion of Northmen and Celts in the 9th and 10th centuries, while there are in the poems themselves traces of Celtic mythology, language and manners.

Many of these poems were Englished in prose by the translator of Mallet, by B. Thorpe in his *Saemund's Edda*, and two or three by Messrs. Morris and Magnússon, as appendices to their translation of *Völsunga Saga*. Earlier translations in verse are those in Dryden's *Miscellany* (vol. vi.), A. Cottle's *Edda*, Mathias's *Translations*, and W. Herbert's *Old Icelandic Poetry*. Gray's versions of *Darrafar-ljóð* and *Vegtamskviða* are well known.

When one turns to the early poetry of the Scandinavian continent, preserved in the rune-staves on the memorial stones of Sweden, Norway and Denmark, in the didactic *Hávamál*, the *Great Volsung Lay* (i.e., Sigurd II., Fafnis's Lay, Sigdrifa's Lay) and *Hamðsmál*, all continental, and all entirely consonant to the remains of Old English poetry in metre, feeling and treatment, one can see that it is with this school that the Icelandic "makers" are in sympathy, and that from it their verse naturally descends. While shrewdness, plain straightforwardness, and a certain stern way of looking at life are common to both, the Icelandic school adds a complexity of structure and ornament, an elaborate mythological and enigmatical phraseology and a regularity of rhyme, assonance, luxuriance, quantity and syllabification, which it caught from the Latin and Celtic poets, and adapted with exquisite ingenuity to its own main object, that of securing the greatest possible beauty of sound.

G. Vigfússon first promulgated the idea that the Eddic poems originated in the British isles, whether in the Northern and Western isles, or, as he later thought, in the Channel islands. Sophus Bugge, in *The Home of the Eddic Poems*, has attempted to show from internal evidence "that the oldest, and, indeed, the great majority of both the mythological and heroic poems were composed by Norwegians in the British isles, the greater number perhaps in northern England, but some, it may be, in Ireland, in Scotland, or in the Scottish isles." Finnur Jónsson holds that the great majority of the poems were composed in Norway, while Björn M. Olsen claims that most of them were composed by Icelanders. But, wherever the poems may have had their origin, they were evidently the work of men who were in contact with the civilizations of England and Ireland and were strongly influenced by the English and Irish literatures.

Early Icelandic Poets.—The first generations of Icelandic poets resemble in many ways the later troubadours; the books of the kings and the sagas are full of their strange lives. Men of good birth (nearly always, too, of Celtic blood on one side at least), they leave Iceland young and attach themselves to the kings and earls of the north, living in their courts as their henchmen, sharing their adventures in weal and woe, praising their victories, and hymning their deaths if they did not fall by their sides—men of quick passion, unhappy in their loves, jealous of rival poets and of their own fame, ever ready to answer criticism with a satire or with a sword-thrust, but clinging through all to their art, in which they attained most marvellous skill.

Such men were Egil, the foe of Eirik Bloodaxe and the friend of Aethelstan; Kormák, the hot-headed champion; Eyvind, King Haakon's poet, called *Skaldaspillir*, because he copied in his dirge over that king the older and finer *Eiríksmál*; Gunnlaug, who sang at Aethelred's court, and fell at the hands of a brother bard, Hrafn; Hallfred, Olaf Trygvason's poet, who lies in Iona by the

side of Macbeth; Sighvat, St. Olaf's henchman, most prolific of all his comrades; Thormod, Coalbrow's poet, who died singing after Sticklastad battle; Ref, Ottar the Black, Arnor the earls' poet, and, of those whose poetry was almost confined to Iceland, Gretti, Biorn the Hitdale champion, and the two model Icelandic masters, Einar Skulason and Markus the Lawman, both of the 12th century.

It is impossible to do more here than mention the names of the most famous of the long roll of poets which are noted in the works of Snorri and in the two *Skálda-tal*. They range from the rough and noble pathos of Egil, the mystic obscurity of Kormák, the pride and grief of Hallfred, and the marvellous fluency of Sighvat, to the florid intricacy of Einar and Markus.

The art of poetry stood for the Icelanders in lieu of music; scarcely any prominent man but knew how to turn a mocking or laudatory stanza, and down to the fall of the commonwealth the accomplishment was in high request. In the literary age the chief poets belong to the great Sturlung family, Snorri and his two nephews, Sturla and Olaf, the White Poet, being the most famous "makers" of their day. Indeed, it is in Snorri's *Edda*, a poetic grammar of a very perfect kind, that the best examples of the whole of northern poetry are to be found. The last part, *Háttatal*, a treatise on metre, was written for Earl Skuli about 1222, in imitation of Earl Rognvald and Hall's *Háttalykill* (*Clavis metrica*) of 1150. The second part, *Skáldskaparmál*, a gradus of synonyms and epithets, which contains over 240 quotations from 65 poets, and ten anonymous lays—a treasury of verse—was composed c. 1230. The first part, an exquisite sketch of northern mythology, *Gylfa-ginning*, was probably prefixed to the whole later. There is some of Sturla's poetry in his *Islendinga Saga*, and verses of Snorri occur in the *Grammatical Treatise* on figures of speech, etc., of Olaf, which contains about 140 quotations from various authors, and was written about 1250.

Besides those sources, the *Kings' Lives* of Snorri and later authors contain a great deal of verse by Icelandic poets. King Harold Sigurdsson, who fell at Stamford Bridge 1066, was both a good critic and composed himself. Many tales are told of him and his poet visitors and henchmen. The Icelandic sagas also comprise much verse which is partly genuine, partly the work of the 12th and 13th century editors. Thus there are genuine pieces in *Nial's Saga* (chaps. 34, 78, 103, 126, 146), in *Eyrbyggja*; *Laxdæla*, *Egil's Saga* (part only), *Grettla* (two and a half stanzas, cf. *Landnámabók*), *Biorn's Saga*, *Gunnlaug's Saga*, *Havard's Saga*, *Kormak's Saga*, *Viga-Glum's Saga*, *Erik the Red's Saga* and *Póstbræðra Saga*. In *Nial's*, *Gisli's* and *Droplaug's Sons' Sagas* there is good verse of a later poet, and in many sagas worthless rubbish foisted in as ornamental.

To these may be added two or three works of a semi-literary kind, composed by learned men, not by heroes and warriors. Such are *Konunga-tal*, *Hugsvinns-mál* (a paraphrase of Cato's *Distichs*), *Merlin's Prophecy* (paraphrased from Geoffrey of Monmouth by Gunnlaug the monk), *Jónsvíkinga-drápa* (by Bishop Ketil), and the *Islendinga-drápa*, which has preserved brief notices of several lost sagas concerning Icelandic worthies, with which *Guðmundar-drápa*, though of the 14th century, may be also placed.

Rímur.—Just as the change of law gave the death-blow to an already perishing commonwealth, so the rush of mediaeval influence, which followed the union with Norway, completed a process which had been in force since the end of the 11th century, when it overthrew the old Icelandic poetry in favour of the *rímur*.

The introduction of the *danz*, ballads (or *fornkvæði*, as they are now called) for singing, with a burden, usually relating to a love-tale, which were immensely popular with the people and performed by whole companies at weddings, yule feasts and the like, had relegated the regular Icelandic poetry to more serious events or to the more cultivated of the chiefs. But these "jigs," as the Elizabethans would have called them, dissatisfied the popular ear in one way: they were, like old English ballads, which they closely resembled, in rhyme, but void of alliteration, and accordingly they were modified and replaced by the *rímur*, the staple

literary product of the 15th century. These were rhymed but also alliterative, in regular form, with prologue or *mansong* (often the prettiest part of the whole), main portion telling the tale (mostly derived in early days from the French romances of the Carolingian, Arthurian or Alexandrian cycles, or from the mythic or *skrók-sögur*), and epilogue. Their chief value to us lies in their having preserved versions of several French poems now lost, and in their evidence as to the feelings and bent of Icelanders in the "Dark Age" of the island's history. The ring and melody which they all possess is their chief beauty.

Of the earliest, *Oláfsríma*, by Einar Gilsson, (c. 1350), and the best, the Aristophanic *Skiða-ríma* (c. 1430), by Einar Fostri, the names may be given. *Rímur* on sacred subjects were called *diktur*; of these, on the legends of the saints' lives, many remain. The most notable of its class is the *Lilja* of Eysteinn Asgrímsson, a monk of Holyfell (c. 1350), a most "sweet sounding song." Later the poems of the famous Jon Arason (b. 1484), last Catholic bishop of Hólar (c. 1530), *Ljómur* ("gleams") and *Pislar-grátr* ("passion-tears"), deserve mention. Arason is also celebrated as having introduced printing into Iceland.

Taste has sunk since the old days; but still this *rímur* poetry is popular and genuine. Moreover, the very prosaic and artificial verse of Sturla and the last of the old school deserved the oblivion which came over them, as a casual perusal of the stanzas scattered through *Islandinga* will prove. It is interesting to notice that a certain number of *kenningar* (poetical paraphrases) have survived from the old school even to the present day, though the mass of them have happily perished. The change in the *phoësis* of the language is well illustrated by the new metres as compared with the old Icelandic *drótt-kvaedi* in its varied forms. Most of the older *rímur* and *diktur* are as yet unprinted. Many of the *fornkvaedi* are printed in a volume of the old *Nordiske Litteratur Samfund*.

The effect of the Reformation was deeply felt in Icelandic literature, both prose and verse. The name of Hallgrím Petersson, whose *Passion-hymns*, "the flower of all Icelandic poetry," have been the most popular composition in the language, is foremost of all writers since the second change of faith. The gentle sweetness of thought, and the exquisite harmony of wording in his poems, more than justify the popular verdict. His *Hymns* were finished in 1660 and published in 1666, two great Protestant poets thus being contemporaries. A collection of Reformation hymns, adapted, many of them, from the German, the *Hólar-book*, had preceded them in 1619. There was a good deal of verse-writing of a secular kind, far inferior in every way, during this period. In spite of the many physical distresses that weighed upon the island, ballads (*fornkvaedi*) were still written, ceasing about 1750, *rímur* composed, and more elaborate compositions published.

The most notable names are those of the improvisatore Stephen the Blind; Thorlak Gudbrandsson, author of *Ulfar-Rímur*, d. 1707; John Magnusson, who wrote *Hristafla*, a didactic poem; Stefan Olafsson, composer of psalms, *rímur*, etc., d. 1688; Gunnar Pálsson, the author of *Gunnarslag*, often printed with the Eddic poems, c. 1791; and Eggert Olafsson, traveller, naturalist and patriot, whose untimely death in 1768 was a great loss to his country. His *Búnaðr-bálkur*, a Georgic written, like Tusser's *Points*, with a practical view of raising the state of agriculture, has always been much prized. Paul Vidalin's ditties are very naïve and clever.

Of later poets, down to more recent times, perhaps the best was Sigurd of Broadfirth, many of whose prettiest poems were composed in Greenland like those of Jon Biarnisson before him, c. 1750; John Thorlaksson's translation of Milton's great epic into Eddic verse is praiseworthy in intention, but, as may be imagined, falls far short of its aim. He also turned Pope's *Essay on Man* and Klopstock's *Messiah* into Icelandic. Benedikt Gröndal tried the same experiment with Homer in his *Ilión's Kvaedi*, c. 1825. There is a fine prose translation of the *Odyssey* by Sveinbjörn Egilsson, the lexicographer, both faithful and poetic in high degree.

Sagas.—The real strength of old Icelandic literature is shown

in its most indigenous growth, the "Saga" (see also SAGA). This is, in its purest form, the life of a hero, composed in regular form, governed by fixed rules, and intended for oral recitation. It bears the strongest likeness to the epic in all save its unversified form; in both are found, as fixed essentials, simplicity of plot, chronological order of events, set phrases used even in describing the restless play of emotion or the changeful fortunes of a fight or a storm, while in both the absence of digression, comment or intrusion of the narrator's person is invariably maintained. The saga grew up in the quieter days which followed the change of faith (1002), when the deeds of the great families' heroes were still cherished by their descendants, and the exploits of the great kings of Norway and Denmark handed down with reverence. Telling of stories was a recognized form of entertainment at all feasts and gatherings, and it was the necessity of the reciter which gradually worked them into a regular form, by which the memory was relieved and the artistic features of the story allowed to be more carefully elaborated. That this form was so perfect must be attributed to Irish influence, without which indeed there would have been a saga, but not the same saga. It is to the west that the best sagas belong; it is to the west that nearly every classic writer whose name we know belongs; and it is precisely in the west that the admixture of Irish blood is greatest. In comparing the Irish tales with the saga, there will be felt deep divergencies in matter, style and taste, the richness of one contrasting with the chastened simplicity of the other; the one's half-comic, half-earnest bombast is wholly unlike the other's grim humour; the marvellous, so unearthly in the one, is almost credible in the other; but in both are the keen grasp of character, the biting phrase, the love of action and the delight in blood which almost assumes the garb of a religious passion.

When the saga had been fixed by a generation or two of oral reciters, it was written down; and this stereotyped the form, so that afterwards when literary works were composed by learned men (such as Abbot Karl's *Sverri's Saga* and Sturla's *Islandinga*) the same style was adopted.

Taking first the sagas relating to Icelanders, of which some 35 or 40 remain out of thrice that number, they were first written down on separate scrolls, no doubt mainly for the reciter's convenience, between 1140 and 1220, in the generation which succeeded Ari, and felt the impulse his books had given to writing. They then went through the different phases which such popular compositions have to pass in all lands—editing and compounding (1220–60), padding and amplifying (1260–1300), and finally collection in large mss. (14th century). Sagas exist showing all these phases, some primitive and rough, some refined and beautified, some diluted and weakened, according as their copyists have been faithful, artistic or foolish; for the first generation of mss. have all perished. We have also complex sagas put together in the 13th century out of the scrolls relating to a given locality, such a group as still exists untouched in *Vápnfröðinga* being fused into such a saga as *Níðla* or *Luxdæla*. Of the authors nothing is known; we can only guess that some belong to the Sturlung school. According to subject they fall into two classes, those relating to the older generation before Christianity and those telling of St. Olaf's contemporaries; only two fall into a third generation.

Beginning with the sagas of the west, most perfect in style and form, the earliest in subject is that of *Gold-Thori* (c. 930), whose adventurous career it relates; *Hærrisa-pórrisaga* tells of the burning of Blund-Ketil, a noble chief, an event which led to Thord Gelli's reforms next year (c. 964); *Géslasaga* (960–980) tells of the career and death of that ill-fated outlaw; it is beautifully written, and the verses by the editor (13th century) are good and appropriate; *Hord's Saga* (980) is the life of a band of outlaws on Whalesfirth, and especially of their leader Hord. Of later subject are the sagas of *Havard* and his revenge for his son, murdered by a neighbouring chief (997–1002); of the *Heiðarvígisaga* (990–1015), a typical tale of a great blood feud, written in the most primitive prose; of *Gunnlaug* and *Hrafn* (*Gunnlaugssaga Ormstungu*, 980–1008), the rival poets and their ill-starred love. The verse in this saga is important and interest-

ing. To the west also belong the three great complex sagas *Egla*, *Eyrbyggja* and *Laxdaela*. The first (870-980), after noticing the migration of the father and grandfather of the hero poet Egil, and the origin of the feud between them and the kings of Norway, treats fully of Egil's career, his enmity with Eirik Bloodaxe, his service with Aethelstan, and finally, after many adventures abroad, of his latter days in Iceland at Borg, illustrating very clearly what manner of men those great settlers and their descendants were, and the feelings of pride and freedom which led them to Iceland. The style is that of Snorri, who had himself dwelt at Borg. *Eyrbyggja* (890-1031) is the saga of politics, the most loosely woven of all the compound stories. It includes a mass of information on the law, religion, traditions, etc., of the heathen days in Iceland, and the lives of Eric, the real discoverer of Greenland, Biorn of Broadwick, a famous chief, and Snorri, the greatest statesman of his day. Dr. Vigfússon would ascribe its editing and completion to Sturla the Lawman, c. 1250. *Laxdaela* (910-1026) is the saga of Romance. Its heroine Gudrun is the most famous of all Icelandic ladies. Her love for Kiartan the poet, and his career abroad, his betrayal by his friend Bolli, the sad death of Kiartan at his hands, the revenge taken for him on Bolli, whose slayers are themselves afterwards put to death, and the end of Gudrun, who becomes an anchorite after her stormy life, make up the pith of the story. The contrast of the characters, the rich style and fine dialogue which are so remarkable in this saga, have much in common with the best works of the Sturlung school.

Of the north there are the sagas of *Kormák* (930-960), most primitive of all, a tale of a wild poet's love and feuds, containing many notices of the heathen times; of *Vatzdaelasaga* (890-980), relating to the settlement and the chief family in Waterdale; of *Hallfred* the poet (996-1014), narrating his fortune at King Olaf's court, his love affairs in Iceland, and finally his death and burial at Iona; of *Reyk-daela* (990), which preserves the lives of Askell and his son Viga-Skuti; of *Svarf-daela* (980-990), a cruel, coarse story of the old days, with some good scenes in it, unfortunately imperfect, chapters 1-10 being forged; of *Viga-Glum* (970-990), a fine story of a heathen hero, brave, crafty and cruel. To the north also belong the sagas of *Gretti* the Strong (1010-31), the life and death of the most famous of Icelandic outlaws, the real story of whose career is mixed up with the mythical adventures of Beowulf, here put down to Gretti, and with the late romantic episodes and fabulous folk-tales (Dr. Vigfússon would ascribe the best parts of this saga to Sturla; its last editor, whose additions would be better away, must have touched it up about 1300), and the stories of the *Ljósvetningasaga* (1009-60). Gudmund the Mighty and his family and neighbours are the heroes of these tales, which form a little cycle. The *Banda-mannia* saga (1050-60), the only comedy among the sagas, is also a northern tale; it relates the struggles of a plebeian who gets a chieftancy against the old families of the neighbourhood, whom he successfully outwits; *Öl-kofra þátr* is a later imitation of it in the same humorous strain. The sagas of the north are rougher and coarser than those of the west, but have a good deal of individual character.

Of tales relating to the east there survive the Weapon-firth cycle—the tales of *Thorstein the White* (c. 900), of *Thorstein the Staffsmitten* (c. 985), of *Gunnar Thidrand's Bane* (1000-08) and of the *Weapon-firth Men* (975-990), all relating to the family of Hof and their friends and kin for several generations—and the story of *Hrafnkell Frey's Priest* (c. 960), the most idyllic of sagas and best of the eastern tales. Of later times there are *Droplaug's Sons' Saga* (997-1007), written probably about 1110, and preserved in the uncouth style of the original (a brother's revenge for his brother's death is the substance of it; *Brand-krossa þátr* is an appendix to it), and the tales of *Thorstein Hall o' Side's Son* (c. 1014) and his brother *Thidrandi* (c. 996), which belong to the cycle of *Hall o' Side's Saga*, unhappily lost; they are weird tales of bloodshed and magic, with idyllic and pathetic episodes.

The Nial Saga.—The sagas of the south are either lost or absorbed in that of *Nial* (970-1014), a long and complex story into

which are woven the tales of *Gunnar Nial*, and parts of others, as *Brian Boroimhe*, *Hall o' Side*, etc. It is, whether we look at style, contents or legal and historical weight, the foremost of all sagas. It deals especially with law, and contains the pith and the moral of all early Icelandic history. Its hero Nial, type of the good lawyer, is contrasted with its villain Mo'rd, the example of cunning, chicane and legal wrong doing; and a great part of the saga is taken up with the three cases and suits of the divorce, the death of Hoskuld and the burning of Nial, which are given with great minuteness. The number and variety of its *dramatis personae* give it the liveliest interest throughout. The women Hallgerda, Bergthora and Ragnhild are as sharply contrasted as the men Gunnar, Skarphedin, Flosi and Kari. The pathos of such tragedies as the death of Gunnar and Hoskuld and the burning is interrupted by the humour of the Althing scenes and the intellectual interest of the legal proceedings. The plot, dealing first with the life and death of Gunnar, type of the chivalry of his day, then with the burning of Nial by Flosi, and how it came about, and lastly with Kari's revenge on the burners, is the ideal saga-plot. The author must have been of the east, a good lawyer and genealogist, and have composed it about 1250, to judge from internal evidence. It has been overworked by a later editor, c. 1300, who inserted many spurious verses.

Relating partly to Iceland, but mostly to Greenland and Vinland (N. America), are the *Flóamannasaga* (985-990), a good story of the adventures of Thorgrils and of the struggles of shipwrecked colonists in Greenland, a graphic and terrible picture; and *Eirikssaga rauða* (990-1000), two versions, one northern (Flatey-book), one western, the better (in *Hawk's Book*, and AM. 557), the story of the discovery of Greenland and Vinland (America) by the Icelanders at the end of the 9th century. Later is the *Fóstbraeðrasaga* (1015-30), a very interesting story, told in a quaint romantic style, of Thorgril, the reckless henchman of King Olaf, and how his death was revenged in Greenland by his sworn brother the true-hearted Thormod Coalbrow's poet, who afterward dies at Sticklestad. The tale of *Einar Sokkason* (c. 1125) may also be noticed. The lost saga of *Poet Helgi*, of which only fragments remain, was also laid in Greenland.

Besides complete sagas there are embedded in the *Heimskringla* numerous small *þaettir* or episodes, small tales of Icelanders' adventures, often relating to poets and their lives at the kings' courts; one or two of these seem to be fragments of sagas now lost. Among the more notable are those of *Orm Storo'lfsson*, *Ogmund Dijtt*, *Halldor Snorrason*, *Thorstein Oxfoot*, *Hromund Halt*, *Thorwald Tasaldi*, *Svadi* and *Arnor Herlingar-nef*, *Audum of Westfirth*, *Sneglu-Halli*, *Hrafn of Hrutfiord*, *Hreidar Heimski*, *Gisli Illugison*, *Ivar* the poet, *Gull-Aesu Thord*, *Einar Skulason* the poet, *Mani* the poet, etc.

The forged Icelandic sagas appear as early as the 13th century. They are very poor, and either worked up on hints given in genuine stories or altogether apocryphal.

History.—About the year of the battle of Hastings was born Ari Froði Thorgilsson (1067-1148), one of the blood of Queen Aud, who founded the famous historical school of Iceland, and himself produced its greatest monument in a work which can be compared for value with the English Domesday Book. Nearly all that we know of the heathen commonwealth may be traced to the collections of Ari. It was he too that fixed the style in which history should be composed in Iceland. It was he that secured and put into order the vast mass of fragmentary tradition that was already dying out in his day. And perhaps it is the highest praise of all to him that he wrote in his own "Danish tongue," and so ensured the use of that tongue by the cultured of after generations. Ari's great work is *Konungabók*, or *The Book of Kings*, relating the history of the kings of Norway from the rise of the Yngling dynasty down to the death of Harald Sigurdson in the year of his own birth. This book he composed from the dictation of old men such as Odd Kolsson, from the genealogical poems, and from the various dirges, battle-songs and eulogia of the poets. It is most probable that he also compiled shorter *Kings' Books* relating to Denmark and perhaps to England. The *Konungabók* is preserved under the *Heimskringla* of

Snorri Sturluson, parts of it almost as they came from Ari's hands, for example *Ynglinga* and *Harald Fairhair's Saga*, and the prefaces stating the plan and critical foundations of the work, parts of it only used as a framework for the magnificent superstructure of the lives of the two Olafs, and of Harald Hardrada and his nephew Magnus the Good. The best text of Ari's *Konungabók* (*Ynglinga*, and the sagas down to but not including Olaf Tryggvason's) is that of *Frisbók*.

The *Book of Settlements* (*Landnámabók*) is a wonderful performance, both in its scheme and carrying out. It is divided into five parts, the first of which contains a brief account of the discovery of the island; the other four, one by one taking a quarter of the land, describe the name, pedigree and history of each settler in geographical order, notice the most important facts in the history of his descendants, the names of their homesteads, their courts and temples, thus including mention of 4,000 persons, one-third of whom are women, and 2,000 places. The mass of information contained in so small a space, the clearness and accuracy of the details, the immense amount of life which is breathed into the whole, astonish the reader, when he reflects that this colossal task was accomplished by one man, for his collaborator Kolsegg merely filled up his plan with regard to part of the east coast, a district with which Ari in his western home at Stad was little familiar. *Landnámabók* has reached us in two complete editions, one edited by Sturla, who brought down the genealogies to his own grandfather and grandmother, Sturla and Gudny, and one by Hawk, who traces the pedigrees still later to himself.

Ari also wrote a *Book of Icelanders* (*Islendingabók*, c. 1127), which has perished as a whole, but fragments of it are embedded in many sagas and *Kings' Lives*; it seems to have been a complete epitome of his earlier works, together with an account of the constitutional history, ecclesiastical and civil, of Iceland. An abridgement of the latter part of it, the little *Libellus Islandorum* (to which the title of the bigger *Liber—Islendingabók*—is often given), was made by the historian for his friends Bishops Ketil and Thorlak, for whom he wrote the *Liber* (c. 1137). This charming little book is, with the much later collections of laws, our sole authority for the Icelandic constitution of the commonwealth, but, "much as it tells, the lost *Liber* would have been of still greater importance." *Kristni-Saga*, the story of the christening of Iceland, is also a work of Ari's, "overlaid" by a later editor, but often preserving Ari's very words. This saga, together with several scattered tales of early Christians in Iceland before the change of faith (1002), may have made up a section of the lost *Liber*. Of the author of these works little is known. He lived in quiet days a quiet life; but he shows himself in his works, as Snorri describes him, "a man wise, of good memory and a speaker of the truth." If Thucydides is justly accounted the first political historian, Ari may be fitly styled the first of scientific historians.

A famous contemporary and friend of Ari is Saemund (1056–1131), a great churchman, whose learning so impressed his age that he got the reputation of a magician. He was the friend of Bishop John, the founder of the great Odd-Verjar family, and the author of a *Book of Kings* from Harald Fairhair to Magnus the Good, in which he seems to have fixed the exact chronology of each reign. It is most probable that he wrote in Latin. The idea that he had anything to do with the poetic *Edda* in general, or the *Sun's Song* in particular, is unsupported by evidence.

The flame which Ari had kindled was fed by his successors in the 12th century. Eirik Oddsson (c. 1150) wrote the lives of Sigurd Evil-deacon and the sons of Harold Gille, in his *Hryggjar-Stykki* (Sheldrake), of which parts remain in the mss. collections of *Kings' Lives*, *Morkin-skinna*, etc. Karl Jonsson, abbot of Thingore, the Benedictine minster, wrote (c. 1184) *Sverrissaga* from the lips of that great king, a fine racy biography, with a style and spirit of its own. *Böglunga-Sögur* tell the story of the civil wars which followed Sverri's death. They are probably by a contemporary.

The Latin *Lives of St. Olaf*, Odd's in Latin (c. 1175), compiled from original authorities, and the *Legendary Life*, by another

monk whose name is lost, are of the mediaeval Latin school of Saemund to which Gunnlaug belonged.

Snorri's Heimskringla.—Snorri Sturluson (q.v.) was known to his contemporaries as a statesman and poet; to us he is above all an historian. Snorri (1179–1241) wrote the *Lives of the Kings* (*Heimskringla*), from Olaf Tryggvason to Sigurd the Crusader inclusive; and we have them substantially as they came from his hand in the *Great King Olaf's Saga*; *St. Olaf's Saga*, as in *Heimskringla* and the Stockholm ms.; and the succeeding *Kings' Lives*, as in *Hulda* and *Hrokkinskinna*, in which, however, a few episodes have been inserted.

These works were indebted for their facts to Ari's labours, and to sagas written since Ari's death; but the style and treatment of them are Snorri's own. The fine Thucydidean speeches, the dramatic power of grasping character, and the pathos and poetry that run through the stories, along with a humour such as is shown in the *Edda*, and a varied grace of style that never flags or palls, make Snorri one of the greatest of historians.

Here it should be noticed that *Heimskringla* and its class of mss. (*Eirspennil*, *Jöfraskinna*, *Gullinskinna*, *Fris-bók* and *Kringla*) do not give the full text of Snorri's works. They are abridgements made in Norway by Icelanders for their Norwegian patrons, the *Life of St. Olaf* alone being preserved intact, for the great interest of the Norwegians lay in him, but all the other *Kings' Lives* being more or less mutilated, so that they cannot be trusted for historic purposes; nor do they give a fair idea of Snorri's style.

Ágrip is a 12th-century compendium of the *Kings' Lives* from Harald Fairhair to Sverri, by a scholastic writer of the school of Saemund. As the only Icelandic abridgement of Norwegian history taken not from Snorri but sources now lost, it is of worth. Its real title is *Konunga-tal*.

Nóregs Konunga-tal, now called *Fagrskinna*, is a Norse compendium of the *Kings' Lives* from Halfdan the Black to Sverri's accession, probably written for King Haakon, to whom it was read on his death-bed. It is an original work, and contains much not found elsewhere. As non-Icelandic it is only noticed here for completeness.

Styrmi Karason, a contemporary of Snorri's, dying in 1245, was a distinguished churchman (lawman twice) and scholar. He wrote a *Life of St. Olaf*, now lost; his authority is cited. He also copied out *Landnámabók* and *Sverri's Life* from his mss., of which surviving copies were taken.

Sturla, Snorri's nephew, wrote the *Hákonssaga* and *Magnússaga* at the request of King Magnus, finishing the first c. 1265, the latter c. 1280. King Haakon's *Life* is preserved in full; of the other only fragments remain. These are the last of the series of historic works which Ari's labours began, from which the history of Norway for 500 years must be gathered.

A few books relating the history of other Scandinavian realms will complete this survey. In *Skjöldunga-bók* was told the history of the early kings of Denmark, perhaps derived from Ari's collections, and running parallel to *Ynglinga*. The earlier part of it has perished save a fragment *Sögu-brot*, and citations and paraphrases in Saxo, and the mythical *Ragnar Lodbrok's* and *Gongu-Hrolf's Sagas*; the latter part, *Lives of Harold Bluetooth and the Kings down to Sveyn II.*, is still in existence and known as *Skjöldunga*.

The *Knútssaga* is of later origin and separate authorships, parallel to Snorri's *Heimskringla*, but earlier in date. The *Lives of King Valdemar and his Son*, written c. 1185, by a contemporary of Abbot Karl's, are the last of this series. The whole were edited and compiled into one book, often quoted as *Skjöldunga*, by a 13th century editor, possibly Olaf, the White Poet, Sturla's brother, guest and friend of King Valdemar II. *Jómsvíkinga Saga*, the history of the pirates of Jom, down to Knut the Great's days, also relates to Danish history.

The complex work now known as *Orkneyinga* is made up of the *Earls' Saga*, lives of the first great earls, Turf-Einar, Thorfinn, etc.; the *Life of St. Magnus*, founded partly on Abbot Robert's Latin life of him (c. 1150) an Orkney work, partly on Norse or Icelandic biographies; a *Miracle-book* of the same saint; the *Lives of Earl Rognwald and Sveyn*, the last of the vikings, and

a few episodes such as the *Burning of Bishop Adam*. A scholastic sketch of the rise of the Scandinavian empire, the *Foundation of Norway*, dating c. 1120, is prefixed to the whole.

Faereyinga tells the tale of the conversion of the Faereys or Faroes, and the lives of its chiefs Sigmund and Leif, composed in the 13th century from their separate sagas by an Icelander of the Sturlung school.

Biographies.—The saga has already been shown in two forms, its original epic shape and its later development applied to the lives of Norwegian and Danish kings and earls, as heroic but deeper and broader subjects than before. In the 13th century it is put to a third use, to tell the plain story of men's lives for their contemporaries, after satisfying which demand it dies away forever.

These biographies are more literary and mediaeval and less poetic than the Icelandic sagas and kings' lives; their simplicity, truth, realism and purity of style are the same. They run in two parallel streams, some being concerned with chiefs and champions, some with bishops. The former are mostly found embedded in the complex mass of stories known as *Sturlunga*, from which Dr. Vigfússon extricated them, and for the first time set them in order. Among them are the sagas of *Thorgils and Hafidi* (1118–21), the feud and peacemaking of two great chiefs, contemporaries of Ari; of *Sturla* (1150–83), the founder of the great Sturlung family, down to the settlement of his great lawsuit by Jon Loptsson, who thereupon took his son Snorri the historian to fosterage—a humorous story but with traces of decadence about it, and glimpses of the evil days that were to come; of the *Örnundar-brennusaga* (1185–1200), a tale of feud and fire-raising in the north of the island, the hero of which, Gudmund Dyri, goes at last into a cloister; of *Hrafn Sveinbjarnarson* (1190–1213), the noblest Icelander of his day, warrior, leech, seaman, craftsman, poet and chief, whose life at home, travels and pilgrimages abroad (Hrafn was one of the first to visit Becket's shrine), and death at the hands of a foe whom he had twice spared, are recounted by a loving friend in pious memory of his virtues, c. 1220; of *Aron Hjörleifsson* (1200–55), a man whose strength, courage and adventures befit rather a henchman of Olaf Tryggvason than one of King Haakon's thanes (the beginning of the feuds that rise round Bishop Gudmund are told here), of the *Svinefell-men* (1248–52), a pitiful story of a family feud in the far east of Iceland.

But the most important works of this class are the *Islendinga Saga* and *Thorgils Saga* of Lawman Sturla. Sturla and his brother Olaf were the sons of Thord Sturluson and his mistress Thora. Sturla was born and brought up in prosperous times, but his manhood was passed in the midst of strife, in which his family fell one by one, and he himself, though a peaceful man who cared little for politics, was more than once forced to fly for his life. While in refuge with King Magnus, in Norway, he wrote his two sagas of that king and his father. After his first stay in Norway he came back in 1271, with the new Norse law-book, and served a second time as lawman. The *Islendinga* must have been the work of his later years, composed at Faerey in Broadfirth, where he died, July 30, 1284, aged about 70 years. The saga of *Thorgils Skardi* (1252–61) seems to have been the first of his works on Icelandic contemporary history; it deals with the life of his own nephew, especially his career in Iceland from 1252 to 1258. The second part of *Islendinga* (1242–62), which relates to the second part of the civil war, telling of the careers of Thord Kakali, Kolbein the Young, Earl Gizur and Hrafn Oddsson. The end is imperfect, there being a blank of some years before the fragmentary ending to which an editor has affixed a notice of the author's death. The first part of *Islendinga* (1202–42) tells of the beginning and first part of the civil wars, the lives of Snorri and Sighvat, Sturla's uncles, of his cousin and namesake Sturla Sighvatsson, of Bishop Gudmund, and Thorwald Gizursson,—the fall of the Sturlungs, and with them the last hopes of the great houses to maintain the commonwealth, being the climax of the story.

Sturla's power lies in his faithfulness to nature, minute observance of detail and purity of style. The great extent of his subject, and the difficulty of dealing with it in the saga form, are

most skilfully overcome; nor does he allow prejudice or favour to stand in the way of the truth. He ranks below Ari in value and below Snorri in power; but no one else can dispute his place in the first rank of Icelandic writers.

Of the ecclesiastical biographers, an anonymous Skalholt clerk is the best. He wrote *Hungrvaka*, lives of the first five bishops of Skalholt, and biographies of his patron Bishop Paul (*Pálssaga*) and also of St. Thorlak (*Thorlákssaga*). They are full of interesting notices of social and church life. Thorlak was a learned man, and had studied at Paris and Lincoln, which he left in 1161. These lives cover the years 1056–1193. The life of St. John, a great reformer, a contemporary of Thorodd, whom he employed to build a church for him, is by another author (1052–1121). The life of Gudmund (*Guðmundar Saga Góða*), a priest, recounts the early life of this Icelandic Becket till his election as bishop (1160–1202); his after career must be sought out in *Islendinga*. It is written by a friend and contemporary. A later life by Arngrim, abbot of Thingore, written c. 1350, as evidence of his subject's sanctity, tells a good deal about Icelandic life, etc. The lives of Bishops Arni and Lawrence bring down our knowledge of Icelandic history into the 14th century. The former work, *Arna Saga Biskups*, is imperfect; it is the record of the struggles of church and State over patronage rights and glebes, written c. 1315; it now covers only the years 1269–91; a great many documents are given in it, after the modern fashion. The latter, *Lárenzius Saga Biskups*, by his disciple, priest Einar Hafidason, is a charming biography of a good and pious man, whose chequered career in Norway and Iceland is picturesquely told (1324–31). It is the last of the sagas. *Bishop Jon's Table-Talk* (1325–39) is also worth noticing; it contains many popular stories which the good bishop, who had studied at Bologna and Paris, was wont to tell to his friends.

The *Annals* are now almost the sole material for Icelandic history; they had begun earlier, but after 1331 they got fuller and richer, till they end in 1430. The best are *Annales Regii*, ending 1306, *Einar Hafidason's Annals*, known as "Lawman's Annals," reaching to 1392, and preserved with others in *Flatey-book*, and the *New Annals*, last of all. The *Diplomatarium Islandicum*, edited by Jon Sigurdsson, contains what remains of deeds, inventories, letters, etc., from the old days, completing our scanty material for this dark period of the island's history.

Literature of Foreign Origin.—After the union with Norway and change of law genuine tradition died out with the great houses. The ordinary mediaeval literature reached Iceland through Norway, and every one began to put it into a vernacular dress, so neglecting their own classics that but for a few collectors like Lawman Hauk they would have perished entirely.

The Norwegian kings, Haakon Haakonson (c. 1225), and Haakon V. (c. 1305), employed Icelanders at their courts in translating the French romances of the Alexander, Arthur and Charlemagne cycles. Some 40 or 50 of these *Riddara-Sögur* (Romances of Chivalry) remain. They reached Iceland and were eagerly read, many *rimur* being founded on them. Norse versions of *Mary of Brittany's Lays*, the stories of *Brutus* and of *Troy*, and part of the *Pharsalia* translated are also found. The *Speculum Regale*, with its interesting geographical and social information, is also Norse, written c. 1240, by a Halogalander. The computational and arithmetical treatises of Stjorn-Odd, Biarni the Number-skilled (d. 1173), and Hauk Erlendsson the Lawman (d. 1334), and the geography of Ivar Bardsson, a Norwegian (c. 1340), are of course of foreign origin. A few tracts on geography, etc., in Hauk's book, and a *Guide to the Holy Land*, by Nicholas, abbot of Thwera (d. 1158), complete the list of scientific works.

The stories which contain the last lees of the old mythology and pre-history seem to be also non-Icelandic, but amplified by Icelandic editors, who probably got the plots from the Western islands. *Völsunga Saga* and *Hervarar Saga* contain quotations and paraphrases of lays by the Helgi poet, and *Halfr's*, *Ragnar's* and *Asmund Kappabana's Sagas* all have bits of western poetry in them. *Hrolf Kraki's Saga* paraphrases part of *Bjarkamál*; *Hro-mund Gripsson's* gives the story of Helgi and Kara (the lost third of the Helgi trilogy), *Gautrek's*, *Arrow Odd's*, *Frithiof's Sagas*, etc.,

contain shreds of true tradition amidst a mass of later fictitious matter of no worth. With the *Riddara-Sögur* they enjoyed great popularity in the 15th century, and gave matter for many *rimur*. *Thidrik's Saga*, a late version of the Völsung story, is of Norse composition (c. 1230), from north German sources.

The mediæval religious literature of western Europe also influenced Iceland, and the *Homilies* (like the *Laws*) were, according to Thorodd, the earliest books written in the vernacular, antedating even Ari's histories. The lives of the *Virgin*, the *Apostles* and the *Saints* fill many mss. (edited in four large volumes by Prof. Unger), and are the works of many authors, chiefly of the 13th and 14th centuries; amongst them are the lives of *SS. Edward the Confessor*, *Oswald of Northumbria*, *Dunstan* and *Thomas of Canterbury*. Of the authors we know Priest Berg Gunsteinsson (d. 1211); Kygri-Biorn, bishop-elect (d. 1237); Bishop Brand (d. 1264); Abbot Runolf (d. 1307); Bishop Lawrence's son Arni (c. 1330); Abbot Berg (c. 1340), etc. A paraphrase of the historical books of the Bible was made by Bishop Brand (d. 1264), called *Gyðinga Sögur*. About 1310 King Haakon V. ordered a commentary on the Bible to be made, which was completed down to Exodus xix. To this Brand's work was afterwards affixed, and the whole is known as *Stjórn*. The Norse version of the famous *Barlaam and Josaphat*, made for Prince Haakon (c. 1240), must not be forgotten.

Post-classical Literature.—The post-classical literature falls chiefly under three heads—religious, literary and scientific. Under the first comes foremost the noble translation of the New Testament by Odd Gottskalksson, son of the bishop of Hólar. Brought up in Norway, he travelled in Denmark and Germany, and took upon him the new faith before he returned to Iceland, where he became secretary to Bishop Ogmund of Skalholt. Here he began by translating the Gospel of Matthew into his mother-tongue in secret. Having finished the remainder of the New Testament at his own house at Olves, he took it to Denmark, where it was printed at Roskild in 1540. Odd afterwards translated the Psalms, and several devotional works of the day, Corvinus's *Epistles*, etc. He was made lawman of the north and west, and, while travelling in his districts, was drowned in the river Laxá in Kjós, June 1556. Three years after his death the first press was set up in Iceland by John Matthewson, at Breidabolstad, in Hunafloe, and a *Gospel and Epistle Book*, according to Odd's version, issued from it in 1562. In 1584 Bishop Gudbrand, who had brought over a splendid font of type from Denmark in 1575 (which he completed with his own hands), printed a translation of the whole Bible at Hólar, incorporating Odd's versions and some books (Proverbs and the Son of Sirach, 1580) translated by Bishop Gizar, but supplying most of the Old Testament himself. This fine volume was the basis of every Bible issued for Iceland till 1826, when it was replaced by a bad modern version. For beauty of language and faithful simplicity of style, the finer parts of this version, especially the New Testament, have never been surpassed.

The most notable theological work Iceland ever produced is the *Postil-Book* of Bishop John Vidalin (1666–1720), whose bold homely style and stirring eloquence made "John's Book," as it is lovingly called, a favourite in every household, till in the 19th century it was replaced for the worse by the more sentimental and polished Danish tracts and sermons. Theological literature is very popular, and many works on this subject, chiefly translations, will be found in the lists of Icelandic bibliographers.

The first modern scientific work is the *Iter per patriam* of Eggert Olafsson and Biarni Paulsson, which gives an account of the physical peculiarities—fauna, flora, etc.—of the island as far as could be done at the date of its appearance, 1772. The island was first made known to "the world" by this book and by the sketch of Unno von Troil, a Swede, who accompanied Sir Joseph Banks to Iceland in 1772, and afterwards wrote a series of "letters" on the land and its literature, etc. This tour was the forerunner of an endless series of "travels," of which those of Sir W. J. Hooker, Sir G. S. Mackenzie (1810), Ebenezer Henderson (1818), Joseph Paul Gaimard (1838–43), Paijkull (1867), and, lastly, that of Sir Richard Burton, an excellent account of the land and people, full of information (1875), are the best.

Iceland is emphatically a land of proverbs, while of folk-tales, those other keys to the people's heart, there is plentiful store. Early work in this direction was done by Jon Gudmundsson, Olaf the Old and John Olafsson in the 17th century, who all put traditions on paper, and their labours were completed by the magnificent collection of Jon Arnason (1862–64), who was inspired by the example of the Grimms. Many tales are but weak echoes of the sagas; many were family legends, many are old fairy tales in a garb suited to their new northern home; but besides all these, there are a number of traditions and superstitions of indigenous origin.

The Renaissance of Iceland dates from the beginning of the 17th century, when a school of antiquaries arose. Arngrim Jonsson's *Brevis Commentarius* (1593), and *Crymogaea* (1609), were the first-fruits of this movement, of which Bishops Odd, Thorlak and Bryniulf (worthy parallels to Parker and Laud) were the wise and earnest supporters. The first (d. 1630) collected much material for church history. The second (d. 1656) saved *Sturlunga* and the *Bishops' Lives*, encouraged John Egilsson to write his *New Hungerwaker*, lives of the bishops of the Dark Ages and Reformation, and helped Biorn of Skardsa (d. 1655), a bold and patriotic antiquary (whose *Annals* continue Einar's), in his researches. The last (d. 1675) collected a fine library of mss., and employed the famous copyist John Erlendsson, to whom and the bishop's brother, John Gizurarson (d. 1648), we are indebted for transcripts of many lost mss.

Torfaeus (1636–1719) and Bartholin, a Dane (d. 1690), roused the taste for northern literature in Europe, a taste which has never since flagged; and soon after them Arni Magnusson (1663–1730) transferred all that remained of vellum and good paper mss. in Iceland to Denmark, and laid the foundations of the famous library and bequest, for which all Icelandic students are so much beholden. For over 40 years Arni stuck to his task, rescuing every scrap he could lay hands on from the risks of the Icelandic climate and carelessness, and when he died only one good mss. remained in the island. Besides his magnificent collection, there are a few mss. of great value at Upsala, at Stockholm, and in the old royal collection at Copenhagen. Those in the university library in the latter city perished in the fire of 1728. Sagas were printed at Upsala and Copenhagen in the 17th century, and the Arnarnæan fund has been working since 1772. In that year appeared also the first volume of Bishop Finn Jonsson's *Historia Ecclesiastica Islandiæ*, a work of high value and much erudition, containing not only ecclesiastical but civil and literary history, illustrated by a well-chosen mass of documents, 870–1740. It has been continued by Bishop P. Peterson to modern times, 1740–1840. The results, however, of modern observers and scholars must be sought for in the periodicals, *Safn*, *Félagsrit*, *Ný Félagsrit* and others. John Espolin's *Islands Arboekur* is very good up to its date, 1832.

A brilliant sketch of Icelandic classic literature is given by Dr. Gudbrand Vigfússon in the Prolegomena to *Sturlunga Saga* (1879). It replaces much earlier work, especially the *Sciagraphia* of Halldan Einarsson (1777), and the *Saga-Bibliothek* of Müller. The numerous editions of the classics by the Icelandic societies, the Danish Société des Antiquités, Nordisk Litteratur Samfund, and the new Gammel Nordisk Litteratur Samfund, the splendid Norwegian editions of Unger, the labours of the Icelanders Sigurdsson and Gislason, and of those foreign scholars in Scandinavia and Germany who have thrown themselves into the work of illustrating, publishing and editing the sagas and poems (men like P. A. Munch, S. Bugge, F. W. Bergmann, Th. Möbius and K. von Maurer, to name only a few), can only be referred to here. See also Finnur Jónsson, *Den Oldnorske og Oldislandske Litteraturs Historie* (1893–1900); R. B. Anderson's translation (Chicago, 1884) of Winkel Horn's *History of the Literature of the Scandinavian North*; and W. Morris and E. Magnússon's *Saga Library*. (F. Y. P.; R. P. Co.)

RECENT LITERATURE

The recent literature of Iceland has been in a more flourishing state than ever before since the 13th century. Lyrical poetry is by far the largest and most interesting portion of it. The great influence of Jónas Hallgrímsson (1807–45) is still felt, and his school was the reigning one up to the end of the 19th century, although then a change seemed to be in sight. The most successful poet of this school is Steingrímur Thorsteinsson (1830–1913).

He is specially famous for his splendid descriptions of scenery (*The Song of Gílsbakki*), his love-songs and his sarcastic epigrams. As a translator he has enriched the literature with *The Arabian Nights*, *Sakuntala*, *King Lear* and several other masterpieces of foreign literature. Equal in fame is Matthías Jochumsson, who, following another of Jónas Hallgrímsson's many ways, has successfully revived the old metres of the classical Icelandic poets, whom he resembles in his majestic, but sometimes too gorgeous, language. As an artist he is inferior to Steingrímur Thorsteinsson, but surpasses him in bold flight of imagination. He has successfully treated subjects from Icelandic history *Grettisljóð*, a series of poems about the famous outlaw Grettir. His chief fault is a certain carelessness in writing; he can never write a bad poem, but rarely a poem absolutely flawless. He has translated Tegnér's *Frithiofs Saga*, several plays of Shakespeare and some other foreign masterpieces. The great religious poet of Iceland, Hallgrímur Pétursson, has found a worthy successor in Valdemar Briem (b. 1848), whose *Songs of the Bible* are deservedly popular. He is like Matthías Jochumsson in the copious flow of his rhetoric; some of his poems are perfect both as regards form and content, but he sometimes neglects the latter while polishing the former. An interesting position is occupied by Benedikt Gröndal, whose travesties of the old romantic stories, e.g., "The Battle of the Plains of Death," a burlesque on the battle of Solferino, and his Aristophanic drama *Gandreiðin* ("The Magic Ride") about contemporary events, are among the best satirical and humorous productions of Icelandic literature.

Influenced by Jónas Hallgrímsson with regard to language and poetic diction, but keeping unbroken the traditions of Icelandic mediaeval poetry maintained by Sigurður Breiðfjörð (1798-1846), is another school of poets, very unlike the first. In the middle of the 19th century this school was best represented by Hjálmar Jónsson from Bóla (1796-1875), a poor farmer with little education but endowed with great poetical talents, and the author of satirical verses not inferior to those of Juvenal both in force and coarseness. In the last decades of the 19th century this school produced two poets of a very high order, both distinctly original and Icelandic. One is Páll Ólafsson (1827-1906). His songs are mostly written in the mediaeval quatrains (*ferskeytla*), and are generally of a humorous and satirical character; his convivial songs are known by heart by every modern Icelander; and although some of the poets of the present day are more admired, there is none who is more loved by the people. The other is Þorsteinn Erlingsson (b. 1858). His exquisite satirical songs, in an easy and elegant but still manly and splendid language, have raised much discussion. Of his poems may be mentioned *The Oath*, a series of most beautiful ballads, with a tragical love-story of the 17th century as their base, but with many and happy satirical allusions to modern life; *Jörundur*, a long poem about the convict king, the Danish pirate Jørgensen, who nearly succeeded in making himself the master of Iceland, and *The Fate of the Gods* and *The Men of the West* (the Americans), two poems which, with their anti-clerical and half-socialistic tendencies, have caused strong protests from orthodox Lutheran clergy. Near to this school, but still standing apart, is Grímur Thomsen.

In the beginning of the '80s a new school arose—having its origin in the colony of Icelandic students at the University of Copenhagen. They had all attended the lectures of Georg Brandes, the great reformer of Scandinavian literature, and, influenced by his literary theories, they chose their models in the realistic school. This school is very dissimilar from the half-romantic school of Jónas Hallgrímsson; it is nearer the national Icelandic school represented by Páll Ólafsson and Þorsteinn Erlingsson, but differs from those writers by introducing foreign elements hitherto unknown in Icelandic literature, and—especially in the case of the prose-writers—by imitating closely the style and manner of some of the great Norwegian novelists. Their influence brought the Icelandic literature into new roads, and it is interesting to see how the tough Icelandic element gradually assimilates the foreign. Of the lyrical poets, Hannes Hafsteinn (b. 1861) is by far the most important. In his splendid ballad, *The Death of Skarphedinn*, and in his beautiful series of songs describing a voyage

through some of the most picturesque parts of Iceland, he is entirely original; but in his love-songs, beautiful as many of them are, a strong foreign influence can be observed. Among the innovations of this poet we may note a predilection for new metres, sometimes adopted from foreign languages, sometimes invented by himself, a thing practised rarely and generally with small success by the Icelandic poets. Among the many later lyrical poets Einar Benediktsson and St. G. Stephansson, resident in Canada, deserve special mention, both rather heavy in style, but rich in ideas and weighty in thought. Lighter and more elegant in style are David Stefánsson, Stefán frá Hvítadal and Hulda (pseudonym of Unnur Bjarklind).

No Icelandic novelist has as yet equalled Jón Þóróddsen (1819-68). The influence of the realistic school has of late been predominant. The most distinguished writer of that school has been Gestur Pálsson (1852-91), whose short stories with their sharp and biting satire have produced many imitations in Iceland. The best are *A Home of Love* and *Captain Sigurd*. Jónas Jónasson (b. 1856), a clergyman of northern Iceland, has, in a series of novels and short stories, given accurate, but somewhat dry, descriptions of the more gloomy sides of Icelandic country life. His best novel is *Randiðr í Hvassafelli*, an historical novel of the middle ages. Besides these we may mention Torfhildur Hólm, one of the few women who have distinguished themselves in Icelandic literature. Her novels are mostly historical. Of the younger novelists the best are Einar H. Kvaran, Jónas Gudlaugsson and Gunnar Gunnarsson. Guðmundur Fridjónsson, Jón Trausti (pseudonym of Guðmundur Magnússon) and Guðmundur G. Hagalín portray folk life with considerable skill. J. M. Bjarnason and Laura Salverson both reside in Canada and depict the life of the Icelandic settlers there, the latter writing in English, e.g., *The Viking Heart*. The last decade of the 19th century saw the establishment of a permanent theatre at Reykjavík, the precursor of the National Theatre of Iceland, founded and endowed by the Althing early in the third decade of the present century. The poet Matthías Jochumsson wrote several dramas, but their chief merits are lyrical. The most popular of Icelandic dramatists as yet is Indriði Einarsson, whose plays, chiefly historical, in spite of excessive rhetoric, possess a true dramatic value. Jóhann Sigurjónsson wrote one of the most powerful of modern dramas, *Fjalla-Eyvindur*, while Guðmundur Kamban's plays achieved a great success at the Royal Theatre in Copenhagen. The drama, *The Mother-in-Law*, by an Icelandic countrywoman, Kristín Sigfúsdóttir, was produced at Reykjavík and Winnipeg, and is much admired.

In geography and geology Þorvaldur Thoróddsen has acquired a European fame for his researches and travels in Iceland, especially in the rarely-visited interior. Of his numerous writings in Icelandic, Danish and German, the *History of Icelandic Geography* is a monumental work. In history Páll Melsteð's (b. 1812) chief work, the large *History of the World*, belongs to this period, and its pure style has had a beneficial influence upon modern Icelandic prose.

Of the younger historians we may mention Þorkell Bjarnason (*History of the Reformation in Iceland*) Jón Adils, Páll E. Ólason, and Jón Helgason. Jón Þorkelsson (b. 1859), archivist, has rendered great services to the study of Icelandic history and literature by his editions of the *Diplomatarium Islandicum* and *Obituaria Islandica*, and his *Icelandic Poetry in the 15th and 16th Century*, written in Danish, an indispensable work for any student of that period. J. Th. Thoróddsen has written with distinction on geography, and Sigfús Sigfússon on folk-lore. A leading position among Icelandic lexicographers is occupied by Jón Þorkelsson (1822-1904), whose *Supplement til islandske Ordbøger*, an Icelandic-Danish vocabulary (three separate collections), has hardly been equalled in learning and accuracy. Other distinguished philologists are the late rektor of the Latin school at Reykjavík, Björn Magnússon Olsen (*Researches on Sturlunga, Ari the Wise, The Runes in the Old Icelandic Literature*—the last two works in Danish); Finnur Jónsson, professor at the University of Copenhagen (*History of the Old Norwegian and Icelandic Literature*, in Danish, and excellent editions of many old Icelandic classical

works); Valtýr Guðmundsson, lecturer at the University of Copenhagen (several works on the old architecture of Scandinavia) and editor of the influential Icelandic literary and political review, *Eimreiðin* ("The Locomotive"); G. T. Zoëga and Sigfús Blöndal, whose Icelandic-Danish dictionary is the first complete dictionary of modern Icelandic.

A. Craigie, *The Oxford Book of Scandinavian Verse* (1925). (S. B.; R. P. Co.)

ICELAND MOSS, a lichen (*Cetraria islandica*) whose erect or ascending foliaceous habit gives it something of the appearance of a moss, whence probably the name. It is often of a pale chestnut colour, but varies considerably, being sometimes almost entirely greyish white; and grows to a height of from 3 to 4 in., the branches being channelled or rolled into tubes, which terminate in flattened lobes with fringed edges. It grows abundantly in the mountainous regions of northern countries, and it is specially characteristic of the lava slopes and plains of the west and north of Iceland. It is found on the mountains of north Wales, north England, Scotland and south-west Ireland. As met with in commerce it is a light-grey harsh cartilaginous body, almost destitute of colour, and having a slightly bitter taste. It contains about 70% of lichenin or lichen-starch, a body isomeric with common starch, but wanting any appearance of structure. It forms a nutritious and easily digested carbohydrate food; it is not, however, in great request.

ICE MANUFACTURE: see REFRIGERATION AND ICE MANUFACTURE.

ICENI, a race of ancient Britain who occupied the part of England now known as Norfolk and Suffolk. After the death of their king Prasutagus in A.D. 60 the Romans established their authority, and the Iceni were eventually conquered and became part of the Roman Empire. See BOADICEA.

ICE-PLANT, the popular name for *Mesembryanthemum crystallinum* (family Aizoaceae), a hardy annual most effective for rockwork in mild climates. It is a low-growing, spreading, herbaceous plant with the fleshy stem and leaves covered with large glittering papillae which give it the appearance of being coated with ice. It is a dry-country plant, a native of Greece and other parts of the Mediterranean region, the Canary Islands, South Africa and California. *Mesembryanthemum* is a large genus (containing about 350 species) of erect or prostrate fleshy herbs or low shrubs, mostly natives of South Africa, and rarely hardy in the British Isles or the northeastern United States, where they are mostly grown as greenhouse plants. They bear conspicuous white, yellow or red flowers with many petals inserted in the calyx-tube. The thick fleshy leaves are very variable in shape, and often have spiny rigid hairs on the margin. They are essentially sun-loving plants. The best-known member of the genus is *M. cordifolium*, var. *variegatum*, with heart-shaped green and silvery leaves and bright rosy-purple flowers. It is extensively used for edging flower-beds and borders during the summer months. Besides the ice-plant three other species grow on the coast of California, the sea fig or beach strawberry (*M. aequilaterale*), with thick, three-sided leaves, and the small-leaved fig-marigold (*M. nodiflorum*), both native, and also the Hottentot fig (*M. edule*) of South Africa, with fleshy, edible fruit, cultivated as a sand-dune binder but now naturalized along the coast near Los Angeles.

ICE-YACHTING, the sport of sailing and racing ice-boats, is practised in Great Britain, Norway and Sweden to some extent, and is very popular in Holland and on the Gulf of Finland, but its highest development is in the United States and Canada. The Dutch ice-yacht is a flat-bottomed boat resting crossways upon a planking about 3ft. wide and 16ft. long, to which are affixed four steel runners, one each at bow, stern and each end of the planking. The rudder is a fifth runner fixed to a tiller. Heavy mainsails and jibs are generally used and the boat is built more for

safety than for speed. The ice-boat of the Gulf of Finland is a V-shaped frame with a heavy plank running from bow to stern, in which the mast is stepped. The stern or steering runner is worked by a tiller or wheel. The sail is a large lug and the boom and gaff are attached to the mast by travellers. The passengers sit upon planks or rope netting.

In 1879 H. Relyea built the "Robert Scott," which had a single backbone and wire guy-ropes, and it became the model for all American river ice-yachts. Masts were now stepped farther forward, jibs were shortened, booms cut down, and the centre of sail-balance was brought more inboard and higher up, causing the centres of effort and resistance to come more in harmony. The shallow steering-box became elliptical. In 1881 occurred the first race for the American Challenge Pennant, which represents the championship of the Hudson river, the clubs competing including the Hudson river, North Shrewsbury, Orange lake, Newburgh and Carthage Ice-Yacht Clubs. The races are usually sailed five times round a triangle of which each leg measures one mile, at least two of the legs being to windward. Ice-yachts are divided into four classes, carrying respectively 600 sq.ft. of canvas or more, between 450 and 600, between 300 and 450, and less than 300 sq.ft. Ice-yachting is very popular on the Great Lakes, both in the United States and Canada, the Kingston (Ontario) Club having a fleet of over 25 sail. Other important centres of the sport are Lakes Minnetonka and White Bear in Minnesota, Lakes Winnebago and Pepin in Wisconsin, Bar Harbor lake in Maine, the St. Lawrence river, Quinte Bay and Lake Champlain.

A modern ice-yacht is made of a single-piece backbone the entire length of the boat, and a runner-plank upon which it rests at right angles, the two forming a kite-shaped frame. The best woods for these pieces are basswood, butternut and pine. They are cut from the log in such a way that the heart of the timber expands, giving the planks a permanent curve, which, in the finished boat, is turned upward. The two forward runners, usually made of soft cast iron and about 2ft. 7in. long and 2½in. high, are set into oak frames a little over 5ft. long and 5in. high. The runners have a cutting edge of 90°, though a V-shaped edge is often preferred for racing. The rudder is a runner about 3ft. 7in. long, worked by a tiller, sometimes made very long, 7½ft. not being uncommon. This enables the helmsman to lie in the box at full length and steer with his feet, leaving his hands free to tend the sheet. Masts and spars are generally made hollow for racing-yachts and the rigging is pliable steel wire. The sails are of 100z. duck for a boat carrying 400 sq.ft. of canvas. They have very high peaks, short hoists and long booms. The mainsail and jib rig is general, but a double-masted lateen rig has been found advantageous.

An ice-yacht about 40ft. in length will carry six or seven passengers or crew, who are distributed in such a manner as to preserve the balance of the boat. In a good breeze the crew lie out on the windward side of the runner-plank to balance the boat and reduce the pressure on the leeward runner. A course of 20m. with many turns has been sailed on the Hudson in less than 48 minutes, the record for a measured mile with flying start being at the rate of about 72m. an hour. In a high wind, however, ice-yachts often move at the rate of 85 and even 90m. an hour.

See *Ice Sports*, in the "Isthmian Library"; *Skating, Curling, Tobogganing*, etc., in the "Badminton Library."

ICHANG, a treaty port of China on the left bank of the Yang-tze kiang in western Hupeh. Although a relatively small town, with about 60,000 inhabitants, Ichang serves an important economic function in the trade of Szechwan and the Yang-tze Valley. Ten miles above the port begins the rugged country, 350 m. in extent, through which the Yang-tze breaks, in a series of four great limestone gorges and some 60 rapids and whirlpools the grandeur of which has been a favourite theme of many Chinese poets, especially Li-Tai-po. Hence Ichang, as the highest point of uninterrupted navigation, is a transshipment point between steamers and junks plying from Hankow and the special boats designed for the passage of the gorges. Formerly this took place entirely in junks hauled by gangs of coolies over the rapids. Much of the trade is still junk-borne, but in 1909 was inaugurated a

service of small, high-powered flat-bottomed steamers which now carry a large proportion of the cotton, cotton-goods, oils, rice and refined sugar passing upstream. A special insurance on goods sent through the gorges is obtainable at the port. An increasing amount of the downstream trade passes through the new customs office at Wanh sien on the Szechwan side of the gorges. Ichang was opened to foreign trade by the Chefoo Convention of 1876. There is a small foreign settlement between the native city and the sheltered anchorage. In 1926 the total trade of the port was valued at 16,820,989 HK.Tls., made up as follows: net foreign imports: 3,635,347; net Chinese imports: 9,616,893; exports: 3,568,749.

ICHNEUMON, the name applied to a number of small African weasel-shaped mammals belonging to the carnivorous family *Viverridae*, the Indian representatives being known as mongooses (*q.v.*). A large number of species of the genus *Herpestes* are known and range over southern Asia and all Africa, *Ichneumon* also occurring in South Spain. It is covered with long, harsh, tawny-grey fur, darker on the head and along the middle of the back; its legs are reddish and its feet and tail black. It lives largely on rats and mice, birds and reptiles, and for this reason it is domesticated.

THE ICHNEUMON OR EGYPTIAN MONGOOSE

ICHNEUMON-FLY, a general name applied to parasitic insects of the section Ichneumonidea, order Hymenoptera, from the typical genus *Ichneumon*, belonging to the chief family of that section. The species of the families *Ichneumonidae*, *Braconidae*, *Evanidae*, *Proctotrypidae*, and *Chalcididae* are often indiscriminately called "Ichneumons," but the "super-family" of the Ichneumonidea in the classification of W. H. Ashmead contains only the *Evanidae*, the *Stephanidae*, and the large assemblage of insects usually included in the two families of the *Ichneumonidae* and the *Braconidae*. The *Ichneumonidae* proper are one of the most extensive groups of insects. Gravenhorst (1829) described some 1,650 European species, to which many subsequent additions have been made. They have all long narrow bodies; a small free head with long filiform or setaceous antennae, which are never elbowed, and have always more than 16 joints; the abdomen attached to the thorax at its hinder extremity between the base of the posterior coxae, and provided in the female with a straight ovipositor often exerted and very long; and the wings veined, with perfect cells on the disc of the front pair.

Their parasitic habits render these flies of great importance in the economy of nature, as they serve to check any inordinate increase in the numbers of injurious insects. Without their aid it would in many cases be impossible for the agriculturist to hold his own against the ravages of his minute insect foes, whose habits are not sufficiently known to render artificial checks or destroying agents available. The females deposit their eggs in or on the eggs, larvae or pupae of other insects of all orders, chiefly *Lepidoptera*, the caterpillars of butterflies and moths being specially attacked (as also are spiders). Anyone who has watched insect life during the summer can hardly have failed to notice the busy way in which the parent ichneumon, a small four-winged fly, with constantly vibrating antennae, searches for her prey; and the clusters of minute cocoons round the remains of some cabbage-butterfly caterpillar must also have been observed by many. This is the work of *Apanteles* (or *Microgaster*) *glomeratus*, one of the *Braconidae*, which in days past was a source of disquietude to naturalists, who believed that the life of the one defunct larva had *transmigrated* into the numerous smaller flies reared from it. Ichneumon-flies which attack external feeders have a short ovipositor, but those attached to wood-feeding insects have that organ of great length to reach the haunts of their concealed prey. Thus a species from Japan (*Bracon penetrator*) has its ovipositor nine times the length of the body; and the large species of *Rhyssa* and *Ephialtes*, parasitic on *Sirex* and large wood-boring beetles in temperate Europe, have very long instruments (with which when handled they will endeavour to sting, sometimes penetrating the

skin), in order to get at their secreted victims. A common reddish-coloured species of *Ophion* (*O. obscurum*), with a sabre-shaped abdomen, is noteworthy from the fact of its eggs being attached by stalks outside the body of the caterpillar of the puss-moth (*Cerura vinula*).

The larvae of the ichneumon-flies are white, fleshy, cylindrical, footless grubs; the majority of them spin silk cocoons before pupating, often in a mass (sometimes almost geometrically), and sometimes in layers of different colours and texture.

The literature on Ichneumon-flies is considerable and technical in character. W. H. Ashmead has written a comprehensive summary on the group (*Proc. U.S. Nat. Mus.* xxiii., 1901) and some account of their parasitic behaviour is given by R. A. Cushman (*Proc. Entom. Soc. Washington*, xxviii., 1925). The British species are described by C. Morley, *Ichneumons of Great Britain* (Plymouth, 1903-14), and T. A. Marshall (*Trans. Entom. Soc.*, 1885-1899).

ICHTNOGRAPHY, an obsolete, architectural term for a horizontal section or plan of a building.

ICHTHYOLOGY, the study of fishes (*see* CYCLOSTOMATA, FISHES, SELACHIANS).

ICHTHYOPHAGI (Gr. for "fish-eaters"), the name given by ancient geographers to several coast-dwelling peoples in different parts of the world and ethnically unrelated. Nearchus mentions such a race as inhabiting the barren shores of the Mekran on the Arabian sea; Pausanias locates them on the western coast of the Red sea. Ptolemy speaks of fish-eaters in Ethiopia, and on the west coast of Africa; while Pliny relates the existence of such tribes on the islands in the Persian gulf.

ICHTHYOSAURIA, a group of extinct reptiles which breathed by lungs but were completely adapted for life in water. They existed during the age of reptiles, the Mesozoic epoch of geology, before the warm-blooded mammals and birds began to flourish, and they filled the place in the seas now occupied by the whales and porpoises. In general, their adaptation to marine life was like that of the modern porpoises, but they never lost their hind pair of limbs, their tail fin was extended in a vertical plane instead of horizontally, and the end of their backbone was always prolonged into this fin. *Ichthyosaurus* (or fish-lizard) itself, which is known by numerous complete skeletons from the Lias, chiefly of England and Germany, is represented not only by the bones but also by the skin and some other soft parts, which are often well preserved in the Upper Lias of Holzmaden, Württemberg. The head is relatively large and tapers forward into a slender, elongated snout. The margins of the head bones are thin and deeply overlapping, as in fishes and porpoises. The eye is very large and surrounded by a rigid ring of sclerotic plates. The teeth, numerous and pointed, are inserted in a single row in a groove in each

FROM THE BRITISH MUSEUM "GUIDE TO FOSSILS, REPTILES AND FISHES"
SKELETON OF THE EXTINCT MARINE REPTILE, ICHTHYOSAURUS COMMUNIS, WITH OUTLINE OF BODY AND FINS; FROM LOWER LIAS OF LYME REGIS, DORSET

jaw. The backbone consists of short biconcave vertebrae which, originally separated by elastic tissue, would produce flexibility like that of the backbone of a fish. There is no neck, and there are no vertebrae modified for contact with the supports of the hinder pair of limbs; the stoutest vertebrae are just in front of the base of the tail fin, and behind this fulcrum the backbone rapidly tapers and is sharply bent downwards to strengthen the lower lobe of the fin. The vertical tail-fin is fan-shaped, without any stiffening rays, and there is a soft triangular median fin on the back. The paired limbs are paddles, with the arm bones (leg

bones) short and pressed together, and the fingers (toes) enclosed in a continuous covering of flesh and skin. The hind-limbs are often relatively small. The tail-fin would be used for progression, while the paired limbs would be for balancing. The skin is known to have been completely smooth. Remains of food in the intestine show that *Ichthyosaurus* fed chiefly on cuttle fishes and fishes, but no example is known showing any spiral marking on the food mass. The isolated spirally marked coprolites commonly ascribed to *Ichthyosaurus* doubtless belong to the associated Hybodont sharks. The skeletons of young within some specimens of *Ichthyosaurus* prove that it was viviparous.

The earliest Ichthyosauria, found in the Triassic rocks of Europe, Spitsbergen and North America, include many comparatively small species not more than a metre in length. Their head bones are less extensively overlapping than in the later forms; the teeth are in separate sockets and not all uniformly conical; the vertebrae are sometimes a little elongated and not deeply concave at the ends; the tail-fin is an elongated flap of skin on the back, not yet fan-shaped; and the limb-bones are comparatively elongated. They therefore suggest that the Ichthyosauria, like the modern whales and porpoises, were descended from land animals. In the Liassic or Lower Jurassic rocks the Ichthyosauria attain their greatest size, being sometimes 10 to 12 metres in length. In the Middle and Upper Jurassic rocks some genera, such as *Ophthalmosaurus* and *Baptanodon*, are almost or completely toothless, and the paddles become extremely flexible owing to the thick layer of cartilage persisting round all their bones. In the Cretaceous rocks, just before their extinction, the Ichthyosauria exhibit their widest geographical distribution, their remains having been found in nearly all parts of the world, from Europe in the north to New Zealand in the south.

See R. Owen, *Monograph of the Fossil Reptilia of the Liassic Formations*, part 3 (Palaeontographical Society, London, 1881); F. von Huene, *Die Ichthyosaurier des Lias* (Berlin, 1922). (A. S. W.)

ICHTHYOSIS or **XERODERMA**, a general thickening of the whole skin and marked accumulation of the epidermic elements, with atrophy of the sebaceous glands, giving rise to a hard, dry, scaly condition. This disease generally first appears in infancy, and is probably congenital. It differs in intensity and in distribution, and is little amenable to treatment. A somewhat similar condition (leukoplakia) affects the tongue in syphilitic subjects and cancer may start in one of the patches.

ICKNIELD STREET. (1) The Saxon name (earlier *Icen-hylt*) of a prehistoric (not Roman) "Ridgeway"—along the Berkshire downs and the Chilterns, which crossed the Thames near Streatley and ended somewhere near Tring or Dunstable. In some places there are traces of a double road, one line on the hills and one in the valley below, as if for summer and winter use. No modern highroad follows it for any distance. Antiquaries have supposed that it once ran on to Royston, Newmarket and Norfolk, where dwelt the Icen, before the Roman conquest. But the name does not occur in early documents so far east, and it has certainly nothing to do with that of the Icen (Haverfield, *Victoria History of Norfolk*, i. 286). (2) A Roman road which ran through Derby, Lichfield, Birmingham and Alcester is sometimes called Icknield Street and sometimes Rycknield Street. The origin of this nomenclature is very obscure.

See *Victoria History of Warwick*, i. 239, and of *Derbyshire*, i. 243; cf., C. Fox, *Archaeology of the Cambridge Region*, and Askins on *A Romano-British Site on Cowbury Hill, Berks*, p. 29 (1916).

ICON, generally any image or portrait-figure. The word is specially applied to the representations in the Eastern Church of sacred personages, which are either flat paintings or in very low relief, sculptured figures being forbidden. (See **BYZANTINE ART**.)

The term "iconography" once confined to the study of engravings is now applied to the history of portrait images in Christian art, though it is also used with a qualifying adjective of Greek, Roman and other art.

ICONIUM (mod. *Konia*), a city of Asia Minor, the last of the Phrygian land towards Lycaonia, was usually attributed to Lycaonia in the Roman time, but retained its old Phrygian connection and population to a comparatively late date. It lies in an

excellently fertile plain, 6 m. from the Pisidian mountains on the west, with mountains more distant on the north and south, while to the east the plain stretches away for hundreds of miles. Streams from the Pisidian mountains aid the cultivation of the land on the south-west and south of the city, and on the east and north-east a great part of the naturally fertile soil has been irrigated since 1914 with water brought from Beyshehr Lake. Trees grow nowhere except in the gardens near the city.

Originally a Phrygian city, as is implied in Acts xiv. 6, it was in a political sense the chief city of the Lycaonian tetrarchy added to the Galatian country about 165 B.C., and it was part of the Roman province Galatia from 25 B.C. to about A.D. 295. Then it was included in the province Pisidia (as Ammianus Marcellinus describes it) till 372, after which it formed part of the new province Lycaonia so long as the provincial division lasted. Later it was a principal city of the theme of Anatolia. It was thrice visited by Paul, probably in A.D. 47, 50 and 53; and it is the principal scene of the tale of Paul and Thecla (which though apocryphal has certainly some historical basis; see **THECLA**). There was a distinct Roman element in Iconium, arising doubtless from the presence of Roman traders. This was recognized by Claudius, who granted the honorary title Claudiconium, and by Hadrian, who elevated the city to the rank of a Roman colony about A.D. 130 under the name Colonia Aelia Hadriana Augusta Iconiensium. In later Roman and Byzantine times it must have been a large and wealthy city. It was a metropolis and an archbishopric, and one of the earliest councils of the Christian church was held there in A.D. 235. The ecclesiastical organization of Lycaonia and the country round Iconium on all sides was complete in the early 4th century, and monuments of later 3rd and 4th century Christianity are extremely numerous. It suffered much from the Arab raids in the three centuries following A.D. 660; its capture in 708 is mentioned, but it never was held as a city of the caliphs. The period of its greatest splendour was after the conquest by the Seljuk Turks about 1072-74. It soon became the capital of the Seljuk state. The palace of the sultans and the mosque of Ala ed-din Kaikobad formerly covered a great part of the Acropolis hill in the northern part of the city. Farther south there is still the great complex of buildings which till recently formed the chief seat of the Mevlevi dervishes, a sect widely spread over Anatolia, but now disbanded; their "Tekke" has been converted into a museum. The walls, about 2 m. in circumference, consisted of a core of rubble and concrete, coated with ancient stones, inscriptions, sculptures and architectural marbles, forming a striking sight. Beyond the walls extended the gardens and villas of a prosperous Oriental population.

When the Seljuk state broke up, and the Osmanli or Ottoman sovereignty arose, Konia decayed. The walls and the palace, still perfect in the beginning of the 19th century, were gradually pulled down for building material, and in 1882 there remained only a small part of the walls, from which all the outer stones had been removed, while the palace was a ruin. At that time and for some years later a large part of Konia was almost deserted. But about 1895 the advent of the Anatolian railway began to restore its prosperity. The water supply was also improved. The sacred buildings were patched up (except a few which were quite ruinous) and the walls wholly removed, but an unsightly fragment of a palace-tower still remained in 1906. In 1904-1905 the first two sections of the Baghdad railway, to Karaman and Ereğli, were built.

Iconium is 389 m. by rail from Smyrna by way of Afium Karahisar. Pop. (1927) 101,674. Carpets are manufactured and mercury is mined.

ICONOCLASTS, breakers of images, a name applied in the 8th and 9th centuries to the opponents of the use of images in Christian worship. (See **ROMAN EMPIRE**, **LATER**.)

At the period of the Reformation (*q.v.*) the name was given to those who advocated the destruction of images in the churches.

ICONOSTASIS, the screen in a Greek, Russian or Armenian church, which encloses the sanctuary. It is generally of masonry, high enough to reach the spring of the vault and extends into the body of the church as far as the easternmost nave pier. In its

nave front there are usually three doors. The face of the screen is often decorated with many tiers of small arcades; each arch encloses the representation of a saint. In Russian churches only the hands, feet and faces of the painted representation or ikon are exposed; the rest of the panel is covered with elaborate, engraved, embossed metal work. In earlier times in Greece, however, the entire image was painted.

ICOSAHEDRON: see SOLIDS, GEOMETRIC.

ICTERUS, a genus of birds belonging to the family, *Icteridae* intermediate between the finches (*q.v.*) and starlings (*q.v.*);

BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

BALTIMORE ORIOLES COMPLETING THE CONSTRUCTION OF THEIR NEST

many of them are called troupials; others are known as the American grackles (*q.v.*). One of the best-known species is *Icterus spurius*, the orchard oriole, an inhabitant of northern South and Central America and the United States. Very many species exist in the Neotropical region, though a few migrate northward in summer. They are nearly all gregarious, many of them with loud and melodious notes, rendering them favourites in captivity. Some have a plumage wholly black, others are richly clad; the well-known Baltimore oriole, golden robin or hangnate of the United States, *Icterus galbula*, has plumage of brightly contrasted black and orange, the tinctures of the armorial bearing of Lord Baltimore, the original grantee of Maryland. The most divergent form of *Icteridae* seems to be that known in the United States as the meadow-lark, *Sturnella magna*, while the bobolink or rice-bird (*q.v.*) with its bunting-like bill, is not much less aberrant.

ICTINUS, Greek architect of the 5th century B.C., was the architect of the Parthenon at Athens, of the Hall of the Mysteries at Eleusis, and of the temple of Apollo Epicurius at Bassae, near Phigalia.

IDA (d. 559), first king of Bernicia, became king in 547, soon after the foundation of the kingdom of Bernicia by the Angles. He built the fortress of Bebbanburgh (Bamborough) and after his death his kingdom, which did not extend south of the Tees, passed in turn to six of his sons. The surname of "Flame-Bearer," sometimes applied to him, refers not to Ida, but to his son Theodoric (d. 587).

IDAHO, the "Gem State," one of the far north-western States of the U.S., is situated between 42° and 49° N. and 111° and 117° W. It is bounded on the north by British Columbia in the Dominion of Canada, on the east by Montana and Wyoming, on the south by Utah and Nevada, and on the west by Oregon and Washington. Its area, of which 534sq.m. are water surface, is 83,880sq.m., or 53,346,560ac. This is about the size of England and Scotland combined, or of New England plus New Jersey. The name is an expression of the Shoshonee Indians, *Ee-dah-how*, meaning, "Look, the sun is coming down the mountain!" It was used by the Indians to arouse the camp in the morning. The popular name "Gem State" is derived from the expression "gem of the mountain," often erroneously given as a translation of the Indian name.

Physical Features.—Idaho lies entirely on the western watershed of the Rocky mountains, and, excepting a small area in the south-east which is drained by Bear river into the Great Salt Lake basin, it is drained by the Columbia river and its branches. The chief of these branches is the Snake river, which takes its rise in Yellowstone park and flows in a great bend south and west nearly 800m. through southern Idaho until it strikes the western border, then flowing northward 200m. farther and forming the boundary between Idaho and Oregon and between Idaho and Washington. At Lewiston it turns abruptly to the west and leaves

the State. Below Idaho Falls for about 600m. of its course its walls are canyon like in character, the river flowing from several hundred to several thousand feet below the level of the plain above. Finally as it flows north it cuts through a mountain range (once a barrier to the Snake, which made all southern Idaho a lake) in the famous Seven Devils canyon, with walls in places 5,000ft. high. Along the Snake's southern and western course are successively Idaho falls, American falls, Twin falls, Shoshone falls, Auger falls and Salmon falls. Shoshone falls are 43 ft. higher than Niagara and did not suffer in comparison with the latter until extensive irrigation diminished the volume of water in the Snake. These falls, together with numberless rapids, some of them miles in length, make the river useless for the transportation of produce, but furnish a tremendous potential water-power supply.

Grazing Land-15%
Mineral Land-9%
Timber-37%

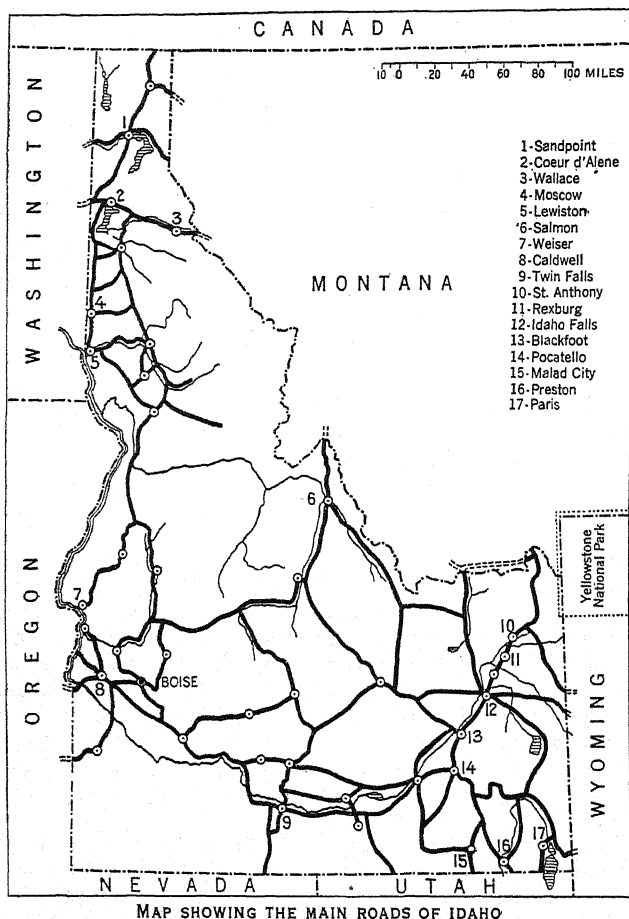

CLASSIFICATION OF LAND—THE TOTAL LAND AREA OF IDAHO IS MORE THAN THAT OF ALL NEW ENGLAND, NEW JERSEY, DELAWARE AND MARYLAND

Bordering the Snake river in a belt 50 to 75m. wide are the Snake river plains, originally arid, desolate sage-brush land, but now irrigated and Idaho's chief agricultural region. These plains were built up by a series of lava sheets from extinct volcanic craters to the north, and the volcanic-ash soil is rich in mineral elements of plant food, such as phosphorous and potash. In the northern plain between Arco and Carey is a district containing about 63 volcanic craters, lava and cinder cones, which was set apart in 1924 as the "Craters of the Moon" national monument. It is a region with weird landscape effects and furnishes the best example of fissure lava flows in North America. South of the plains the land rises to a divide between the Columbia basin and the Great Salt Lake basin. This divide in places breaks into low mountain ranges. In the south-east the Bear river range forms a northern extension of the Wasatch range of Utah. In the south-west the Owyhee mountains and their foothills occupy a large area.

The main mountain system of the State, however, is formed by those ranges (the Cabinet, Coeur d'Alene, Bitter Root and Beaverhead) which lie along the north-east boundary, together with their various spurs extending westward and south-westward toward the central part of the State. From these mountains flow the Salmon and Clearwater rivers, the main branches of the Snake. Through narrow valleys and canyons often impassable, they drain the most thinly settled and the wildest and most rugged section of the State. Most of the region, an area several times larger than Switzerland, is still impenetrable except by pack-horse. Its existence has prevented the construction of a railway connecting north and south Idaho, and not until 1927 was a north and south highway completed. All travel previously between the two settled regions of the State had to pass through Oregon and Washington. The wilderness region is bounded on the south by the Sawtooth mountains, a range which also forms the northern boundary of the Snake river valley. These mountains rival in sublimity any range in the United States. They contain Hyndman peak (12,078ft.), the highest point in Idaho. Other high and beautiful ranges of the region are the Salmon river mountains and the Lost river range. South of the latter are Big Lost river and a number of smaller streams which disappear after reaching the upper Snake river plains in the driest portion of Idaho. North of the Salmon river country is the Clearwater country, through which runs the Lo Lo trail travelled by Lewis and Clark. This trail passes through the largest area of virgin timber still standing in the United States. The whole region furnishes excellent hunting of the white-tail and mule deer, elk, bear, mountain goat and blue and ruffed grouse and other game birds. The State game warden reports deer and moose to be increasing. Beautiful mountain lakes abound in fish and furnish enchanting camping sites. The region is also rich in mineral resources, which

must wait for transportation facilities before they can be profitably developed.

The northern part of the State is low (average 3,000ft.) compared with the average level of the State (5,000ft.), and this low altitude gives it an advantage in climate which offsets its northern position. There are ranges of great height and beauty, but the valleys between are broad and fertile. Towards the Wash-

MAP SHOWING THE MAIN ROADS OF IDAHO

ington boundary in particular, there are many fine farming regions. An abundant rainfall in this northern section (20 to 35 in. annually) makes irrigation unnecessary. Here are the largest and most beautiful of Idaho's lakes—Priest lake, Pend Oreille and Coeur d'Alene. Across this narrow northern portion flow the Clark Fork and Kootenai rivers on their way to join the Columbia. The lowest portion of the State is at Lewiston, where the Snake river leaves the State at an altitude of only 720ft.

The vast extent and varied topography of Idaho give it a number of distinct climate zones. The entire State comes under the modifying influence of the equable climate of the North Pacific ocean and is protected by its great north-eastern mountain barrier from the severe cold waves that sweep the plains east of the continental divide. The mean annual temperature varies from about 36° (coldest region centring in Custer county, around the Sawtooth range) to 55° along the middle reaches of the Snake river. In the lower valleys of the Snake and its tributaries the weather is mild enough for even the more tender fruits. The orchards of this region are becoming famous. Precipitation varies even more than temperature, but in general it is greatest in the mountainous region and least in the open plains. The driest regions are along the great south-west bend of the Snake, in the Lost River country, and in the upper reaches of the Salmon river. Tornadoes and severe storms are virtually unknown.

Government.—Idaho is governed by a constitution adopted in 1889, which went into effect when the State entered the Union, July 3, 1890. From time to time, as new needs and conditions presented themselves, this constitution has been amended, and

by 1925, 27 amendments were in effect.

The executive department is made up of elected and appointed officers, all serving two years. Those elected are the governor, lieutenant governor, secretary of State, State auditor, State treasurer, attorney general, superintendent of public instruction, and inspector of mines. In addition to the usual duties of their offices, these officers serve on the State library commission and on special administrative boards, such as the board of pardons, the board of land commissioners, the board of equalization, the board of canvassers and the board of examiners. In 1919 an act of the legislature grouped 51 bureaus, boards and commissions into nine departments. Later the nine departments were reduced to seven: the departments of agriculture, finance, law enforcement, public investments, public welfare, public works and reclamation. Each department is headed by a commissioner appointed by the governor and responsible directly to him.

The legislature consists of two houses, whose members are elected biennially. A senator is elected from each county, and a representative for every 2,500 votes or fraction thereof exceeding 1,000 in each county. In 1927 there were 44 senators and 68 representatives. The legislature meets at Boise for its regular session the first Monday of January in odd-numbered years. Special sessions may be called by the governor if he decides that they are necessary. A two-thirds vote of the legislature can override the governor's vote.

The judiciary consists of a supreme court, holding five terms yearly, its five justices being elected for six years, and 11 district courts with 16 judges, each holding office for four years. At least two terms of the district court must be held in each county each year. Each county also has a probate court trying lesser cases both of civil and of criminal nature, and normally there are two justices of the peace in each county precinct.

Population.—The first census of Idaho was in 1870, when the population was 14,999; in 1880 it was 32,610; in 1890, 88,548; in 1900, 161,772; in 1910, 325,594; and in 1920, 431,866. The increase between 1900 and 1910 was 101.3%; between 1910 and 1920 it was 32.6%. Basing its calculations upon the latter percentage, the U.S. census bureau estimated the population in 1927 to be 534,000; but probably the percentage of increase had not been maintained. Of the population in 1920, 98.6% was white. The remaining 1.4% was made up of 4,048 Indians (approximately the same number as in 1880), 920 negroes, 585 Chinese and 1,569 Japanese. The Chinese have gradually decreased since placer-mining days, but the Japanese are slowly increasing. Of the Indians 1,760 belong to the Bannock and Shoshone tribes residing on the Fort Hall reservation. These are the most primitive of all the north-western tribes, retaining their old-time tribal customs despite the influences of civilized communities all about them. Only 120 of 470 families on the reservation live in permanent homes. The Nez Percé Indians number about 1,400 and are the most interesting historically as well as the most advanced. They and the Coeur d'Alenes, who number about 650, have always been self-supporting. The land of their reservations has been allotted to individuals of the tribes, instead of being held in common.

GROWTH OF POPULATION 1870-1920, SHOWING TOTAL AND NATIVE WHITE

In the extreme north near Bonner's ferry, are a small band of Kootenai Indians who have no reservation, but settled on homesteads along the Kootenai river.

Of the total population in 1920, 9.2% were foreign born and 11.3% were born of foreign parentage. The Scandinavian countries contributed 9,734 of the foreign born; Great Britain and Ireland, 7,664; Germany, 4,143; and various other countries, less than 1,500 each. The urban population in 1920 was 119,037; the rural population, 312,829. The percentage of urban population had increased from 21.5 in 1910 to 27.6 in 1920. Idaho has 36 in-

corporated cities, of which Boise, the capital, is the largest, with an estimated population of 23,042 in 1925. Pocatello, with a population estimated at 18,335 in 1925, is the metropolis of the eastern part of the State. Burley, Caldwell, Coeur d'Alene, Idaho Falls, Lewiston, Nampa and Twin Falls were the other cities over 5,000 in population.

Finance.—The general fund for ordinary running expenses of the State is derived from an annual tax levied on the counties, a tax on insurance companies, interest on current funds in the State depositories, fees paid by corporations, fees of the departments of the State and other sources. Expenditures from this fund are authorized biennially by the legislature under a budget system. In addition to the general fund there are no less than 75 special funds for particular purposes, each with its income derived as far as possible from its own activities and services. Such, for example, is the game fund, with its income derived from licences, or the highway fund, with much of its income derived from a tax of two cents a gallon on gasoline. The lands for public school endowment and for special institutions are also administered as special funds.

In the biennial period 1924-26 State receipts totalled \$17,995,964; disbursements \$17,905,911. The general fund received \$4,592,855, and disbursed \$4,942,466. The assessed value of the State in 1925 was \$478,686,746, a decrease from \$499,471,287 in 1920. On this assessed value in 1925 a tax of \$1,675,000 (3.4 mills) was levied for the general fund, and \$535,000 (1.2 mills) for special funds. The general tax of 3.4 mills may be compared with that of 7.6 in 1919, 5.5 in 1921, 4.7 in 1923. Despite this tax reduction, the State was gradually reducing a debt which had been increased mainly by highway expenditures. There were still in June, 1926, State bonds outstanding to the amount of \$5,649,500, \$3,420,000 of them being for roads and bridges, \$1,375,000 for a new State capitol, and the rest for other State buildings and institutions.

The value of all property in the State was estimated in 1922 at \$1,534,000,000, as compared with \$579,000,000 in 1912. There were 161 banks in the State in 1925, with total resources of \$91,900,000. Their savings deposits were \$25,539,000 in 1925, a decrease from the \$32,512,000 of 1920, but an increase over the \$24,206,000 of 1924.

Education.—A radical change in the Idaho public school system was made in 1913, when the legislature provided that from the primary grades to the State university the administration should be controlled by a single State board of education instead of six separate boards as it had been. This board consists of six members, five of them appointed by the governor (one each year for a term of five years), the sixth being the State superintendent of public instruction, an *ex officio* member. Besides the elementary and secondary schools, the board has under its supervision the University of Idaho, at Moscow, the State normal schools at Lewiston and Albion, the Idaho Technical institute at Pocatello, the Idaho Industrial school at St. Anthony, and the State school for the deaf and blind at Gooding.

The public school population of Idaho in 1926 was 138,885, a slight decrease from the peak of 141,991 in 1922, but an increase over the 137,756 of 1920. The actual enrolment in 1925-26 was 117,360. There were 4,377 teachers employed, and their average salary was \$1,084.12. Of the total enrolment, 21,730 were pupils in the 78 high schools of the State. Total school expenditure has increased from \$2,175,000 in 1910 to \$8,591,000 in 1920, and \$10,053,454 in 1926. Approximately one-half of this was paid for teachers' salaries. The sources of the current school income for 1926 were State appropriations, \$608,682; county appropriations, \$2,742,654; special school tax, \$4,290,185; and miscellaneous, \$1,518,288. School expenditure in 1926 was \$72.34 per capita of the school population, as compared with \$63.24 in 1920. For the benefit of the common schools, the Federal Government granted 2,963,698 acres of land, now owned and administered by the State. There are special grants also which serve as an endowment for the higher institutions.

Enrolment at the University of Idaho has increased rapidly from 1,435 in 1921-22 to 2,266 in 1925-26. Efforts have been

made to alleviate the resultant overcrowding. A new science hall was completed in 1925 at a cost of \$216,000, and the budget approved for 1927-28 carried an appropriation of \$420,000 for a new library and a new heating plant. In 1926 the faculty was increased by 20 members, making a total staff of 143. The approved budget for maintenance for the biennium 1927-28 was \$2,749,403, as compared with \$2,031,987 for the previous biennium. Of this amount \$1,998,273 came from the State and the rest from Federal appropriations, land endowments, fees, etc. In the Lewiston State Normal School, enrolment for the year 1925-26 was 363; in the Albion State Normal school, it was 387. There is also the College of Idaho, a co-educational, non-sectarian institution under Presbyterian control, at Caldwell, which had 499 students and a teaching staff of 32 in 1924-25.

In 1903 a State library commission was established to manage the travelling library of the State, and to give assistance to any community trying to establish a free reading-room. In 1926 there were over 30,000 books in the library, and 200 cases were in circulation. There is little illiteracy, the State ranking third in the Union in 1920, with a percentage of 1.5. Over half of the illiterates were foreign born.

Charitable and Penal Institutions.—The State penitentiary at Boise, had in 1926 an average of 363 inmates constantly under custody. This, when compared with the average of 280 for the biennium 1923-24, showed an alarming increase and resulted in an acute overcrowding problem. A modern shirt-factory furnished an occupation for two-thirds of the inmates, and was so successful financially that it paid both a small wage to the workers and a large share of the institutional expense. Under the administration of the department of public welfare are an insane asylum (342 inmates in 1926), at Blackfoot; the Northern Idaho Sanitarium (277 inmates in 1926), at Orofino; the Idaho Sanitarium (285 inmates in 1926) for mental defectives, at Nampa; a State sanitarium for invalids, at Lava Hot Springs; and the Soldiers' Home (88 inmates in 1926), at Boise. The State board of education has under its administration an industrial training school for boys and girls (314 in attendance in 1926), at St.

AVERAGE YIELD PER ACRE (1927) OF CERTAIN CROPS IN IDAHO COMPARED WITH AVERAGE FOR U.S. AS 100. IDAHO RANKED FIRST IN 1927 AS TO YIELD PER ACRE OF WHEAT, BEANS, SUGAR BEETS, AND CLOVER SEED; SECOND AS TO YIELD PER ACRE OF POTATOES AND CORN

Anthony, and a school for the deaf and blind (90 enrolled in 1926), at Gooding. There is also at Boise a foundation for homeless children, under private auspices.

Agriculture and Live Stock.—Agriculture and live stock raising—which in Idaho can no longer be separated—rank as the most important industries. Agriculture is of three types, according to the amount of rainfall. In the northern part of the State and in other regions where the rainfall is over 18 in. annually, humid farming can be practised. The cut-over forest lands in the north are among the richest lands of the State. Along the Snake

river irrigation must be relied on entirely, but it has been developed to such an extent that the region produces the largest share of Idaho's crops. Here the soils are volcanic and contain a rich supply of the mineral plant foods. The lack of nitrogen is soon overcome by ploughing in clover and alfalfa crops. Any failure of the irrigation ditches, such as occurred in the abnormally dry year of 1919 and partially in other years, is prevented for the future by the completion in 1926 of the enlarged American falls dam which creates the largest storage reservoir in America. This will hold the spring flood waters of the Snake, which formerly were wasted. On the bench lands and the borders of the Snake river plains, dry farming is carried on extensively. This was the type of agriculture that was expanded most to meet the abnormal demands of the World War years, and it is among dry-land farmers that the largest number of failures have occurred in the subsequent period of depression. The value of farm property increased from \$67,271,000 in 1900 to \$305,317,000 in 1910, and \$716,138,000 in 1920, since when there has been a decrease. The land valued in 1920 at \$511,866,000 was in 1925 valued at only \$310,243,000. The value of buildings and live stock has also decreased, though less disastrously. The number of farms decreased from 42,106 in 1920 to 40,593 in 1925; the acreage, from 8,376,000 to 8,140,000; and farm population, from 200,902 to 172,216. The mortgage debt of Idaho farmers increased from \$14,557,000 in 1910 to \$69,868,000 in 1920, 59% of the farms owned being mortgaged in 1920. Tenants operated 24.4% of the farms in 1925, as compared with 15.9% in 1920. These figures show the agricultural crisis that Idaho has experienced since the World War. In addition to the general depression of prices, it was aggravated there by several exceptionally dry years.

BY COURTESY OF BUREAU OF RECLAMATION
A CONCRETE GRAIN ELEVATOR IN
THE IDAHO WHEAT BELT

The total value of the 22 chief crops in 1919 was \$111,940,000; in 1924, it was \$73,009,000; in 1925, \$103,681,000; and in 1926, \$82,611,000. Wheat and hay are the State's most valuable crops. In 1926 1,045,000 ac. were planted to wheat, yielding approximately 24,633,000 bushels, valued at \$26,173,000. The average yield, 23.5 bushels per acre, is exceptionally high as compared with the averages in such important wheat States as Kansas (14.8), North Dakota (8.0), Montana (12.4) and Minnesota (12.9). In 1926 121,000 tons of hay, 2,768,000 tons of meadow hay, and 2,157,000 tons of alfalfa were harvested, meadow hay yielding an average of 2.7 tons per acre and the alfalfa yielding 3.2 tons. In 1926 66,000 acres of corn (maize) produced 2,706,000 bushels, an average of 41 bushels per ac., which is higher than in any except the Atlantic States, and may be compared with Iowa's average of 37 bushels per acre. In 1926 Idaho produced 4,760,000 bushels of oats and 4,144,000 bushels of barley. Potatoes are an important Idaho crop, and the 1926 production of 16,198,000 bushels was greater than that of any other State west of the Mississippi except Minnesota. The average yield was 178 bushels per acre, an average higher than that of any other State but Maine. The 1925 shipments, totalling 18,271 cars, were exceeded only by those of Maine and Minnesota. Sugar-beet has been an important crop, but low prices have decreased the acreage. Only 17,000 acres were harvested in 1926, as compared with 38,000 acres in 1925.

Idaho has consistently shipped more apples than any other western State except Washington, and the shipments are increasing fast. In 1925 they totalled 7,485 car-loads. The principal varieties are the Jonathan and the Rome Beauty. The principal growing valleys are the Boise and Payette and those around Lewiston. A careful State orchard census in 1924 showed commercial or-

chards (not including home orchards of less than 50 trees) amounting to 27,767 acres, including 956,319 apple trees, 448,495 plum trees, 71,522 peach trees and 73,521 apricot, cherry, and pear trees. Idaho is one of the leading States in output of prunes.

As there are no large consuming centres in Idaho, growers must seek distant markets. These have been opening up rapidly on the Pacific coast, especially in California. This has also stimulated dairying. Milch-cows and heifers increased from 160,000 head in 1925 to 170,000 head in 1927, and their value from \$8,000,000 to \$11,050,000. Creamery butter production rose from 4,660,000 lb. in 1920 to 15,101,000 in 1925. Cheese production rose from 1,722,000 lb. to 7,320,000 lb. in the same years, giving Idaho a rank of fifth among the States in its output.

The sheep-raising industry suffered greatly immediately after the World War. Sheep valued at \$25,309,000 in 1920 dropped in value to \$13,415,000 in 1921. Increased wool prices in 1924, however, aided the industry, and in 1927 Idaho's sheep were valued at \$21,326,000. In 1925, 14,309,000 lb. of wool were shipped, and the estimate for 1926 was 14,507,000 lb. Near Du Bois there is a U.S. sheep experiment station of 44,810 acres, devoted to a study of the problems of range sheep men in the western States.

Mining.—The total value of Idaho's mineral production from the discovery of gold in 1860 to 1927 is estimated at \$1,030,000,000. The leading minerals in the order of their importance are lead, silver, zinc, copper and gold. The annual production of these minerals in the decade before the World War averaged \$24,500,000 in value. During the war the output of lead, silver, zinc and copper, because of the high prices these metals commanded, increased over 100%, but the production of gold decreased 60%. The total mineral production of 1917 was valued at \$54,845,153. After the war the decline in demand and prices, combined with high freight rates and high wages, caused the greatest depression of mining in 20 years. The production for 1921 totalled only \$16,564,014, many of the leading producers suspending operations entirely. Between 1921 and 1926, however, prices of metals slowly increased, so that old mines were reopened and new developments and explorations carried out. By 1925 all the producing mines were maintaining capacity production.

The total value of the five leading metals in 1925 was \$32,971,930, an increase of \$4,394,681 over that of 1924. The increase was mainly in the amount of lead and zinc produced and in the higher prices at which these metals sold, the lead output being worth \$23,930,319, and the zinc \$2,828,573. The silver output decreased slightly, but higher prices gave it a value of \$5,324,178. There was a substantial increase in the production of copper, the 1925 output being \$473,217, but a decided decrease in the production of gold, the 1925 valuation, \$415,640, being the lowest in the State's history. Of the State's mineral production, 92.52% was from the lead-silver-zinc belt of the Coeur d'Alene region in Shoshone county. In 1925 there was a great increase in the number of small producers, which is generally accepted as a sign of health in the mining industry. Most of these were in the southern part of the State. The year was also a good one for labour, the pay-roll being one of the largest in the State's mining history. The average miner's wage increased from about \$4.50 per day in 1921 to \$5.50 in 1925.

The lead, silver and zinc ores are always found associated with each other, and the mining of one can hardly be carried on separately from the other. Much of Idaho's success in mining has been due to milling experiments and inventions which make it possible to treat these complex ores at very little increase in milling costs, giving at the same time high-grade concentrates and increased percentage of recovery.

Only Missouri produced more lead than Idaho until 1925, when Utah with a sudden increase passed ahead. Only Utah and Montana produced more silver. Only a few regions in the State have been thoroughly prospected. Lead-zinc-silver discoveries in the granite areas of Valley and Custer counties in 1925 attracted nation-wide attention. Other known deposits, in remote regions,

await transportation facilities before they can be developed. The mining industry has suffered greatly from speculative promotion, which is now curtailed by "blue sky" laws requiring the filing of all publicity literature, so that some check can be made upon the truth of promoters' claims.

Lumbering.—More than one-third (37%) of Idaho is covered with forests. The total stand of timber has been officially estimated at 98,000,000,000 board ft., of which 58.1% is owned by the Federal Government, 10.7% by the State, and 30.75% by private holders. There are 19 national forests, containing 20,503,893 acres. They were created in 1905, but before this there were many choice areas in private hands, and it has been from these that most of the commercial timber has been cut. In 1923 the cut for the State was 1,073,000,000 board ft.; in 1924 it was 1,018,000,000 board ft. The principal trees in order of their commercial importance are white pine, western or "yellow" pine, spruce, cedar, white fir, larch and red fir.

Manufactures.—Manufacturing in Idaho is built mostly upon the transformation of the raw products of the agricultural, mining and lumbering industries. There were 510 establishments in 1923, employing 15,347 men and paying \$22,886,000 in wages. The value of manufactured products was \$87,429,000, \$44,295,000 of which was added by manufacture. This exceeds the value of any previous year's output, there having been a steady increase since the depression of 1921.

Idaho ranks as the fifth State in the Union in the richness of its water-power resources, so that an ample and cheap supply for future manufacturing is assured. In resources developed, Idaho in 1925 was fourth among the States, 45 plants developing 224,368 h.p. The valuation of all transmission lines in that year was 19,267,718. Water-power resources still undeveloped were estimated by the U.S. geological survey at from 2,262,000 to 5,067,000 horse-power.

History.—Idaho was a part of the "Oregon Country" claimed by Spain, Russia, Great Britain and the United States. Spain relinquished her claims in 1819, Russia in 1824. Great Britain and the U.S. then held the region jointly until a treaty in 1846 gave the U.S. sole possession south of the 49th parallel. The strongest claim of the U.S. was exploration by the Lewis and Clark expedition, the first known white men in Idaho. The expedition found its way across the mountains from Montana by Lemhi Pass in Aug. 1805. The leaders intended to follow to its mouth the first westward stream they encountered, but the impassable canyons along the Salmon forced them to recross the range into Montana. They travelled north through the Bitter Root valley and turned west to re-enter Idaho through Lo Lo Pass. This famous Indian thoroughfare led them down the ridges between the tributaries of the Clearwater river until they reached its navigable waters. Here they built canoes and embarked westward out of the State toward the Columbia. Their return in 1806 was by the same route.

Lewis and Clark were none too early, for in 1809 David Thompson and Finan McDonald, traders of the North-West Company, a British organization, entered Idaho from the north and on the shores of Lake Pend Oreille built a trading post, the first building in the State. In the spring of 1809-10, 46 packs of fur of 90 lb. each were taken out—Idaho's first commercial contribution to the outside world. In 1810 Andrew Henry, of the Missouri Fur company, built the second building in Idaho, on Henry's Fork of the Snake river, the first establishment of a citizen of the U.S. west of the continental divide. Another expedition from the U.S. consisting of 56 men under the command of Wilson Price Hunt, was sent overland to the mouth of the Columbia river by John Jacob Astor, and visited Fort Henry in 1811. Their adventures and disasters in attempting to cross southern Idaho are accurately and vividly told by Washington Irving in *Astoria*. They were the first party to make the trip along the route later followed, in the main, by the Oregon trail.

During the War of 1812 the Americans were forced to give up the region; and with little competition, British traders controlled the fortunes of Idaho for the next 35 years. In 1818 Donald McKenzie was put in charge of the Snake river brigade,

and for four years he led large trapping parties into the region, searching for the best beaver territory. These expeditions were continued for many years by Peter Skene Ogden and John Work, later chiefs of the brigade. Their journals show the thoroughness of their knowledge of the region's topography. In 1834 Nathaniel Wyeth, a Boston man, built Fort Hall on the upper Snake river in an ambitious attempt to establish a trade in the region. To draw away his trade the Hudson's Bay Company built Fort Boise the same year. Both forts later became famous hostleries to emigrants on the Oregon trail.

Movements over this trail began in 1842, when Dr. Elijah White led the first party of 100 to Oregon. Extensive travel began the following year, the first train numbering nearly 1,000 men, women and children. Except for those unfortunates who found graves by the wayside, none of these travellers remained in Idaho, nor did those thousands remain who later crossed south-eastern Idaho on the California trail. It was a back-wave of this emigration, lured by the discoveries of gold in 1860, that was to result in the permanent settling of the State.

Meanwhile, the Rev. Henry Spalding and his wife, sent out by the American Board for Foreign Missions, had established a school for the Indians on Lapwai creek, east of Lewiston (1836), and the first home of a white family where the first white child was born and reared. Seeds were planted in the hope of interesting the Indians in agriculture, and apple trees were set out and irrigating and power ditches were made and used, at the end of which was established and operated a small grist and sawmill. The first printing-press in the Oregon country was brought to Lapwai by pack-horse and set up to print a primer, a hymn-book and the Gospel of Matthew in the Nez Percé language. Father Desmet, the pioneer of Catholicism in the North-west, also established the Sacred Heart mission among the Coeur d'Alene Indians in 1842. In the spring of 1846 William Craig located a few miles up Lapwai creek from the Spalding mission a homestead of 640 ac., under the Oregon donation act, the earliest title in Idaho for which a patent was issued, although the title initiated by the Spalding Mission site ten years earlier was recognized and bought later by the Government before issuance of patent. A Mormon mission and colony had been attempted in the valley of the Lemhi river in 1855, but were recalled by President Young in 1858 because of the hostility of the Bannock and Shoshone Indians. In 1860 a band of Mormon home-seekers made the first permanent agricultural settlement, at Franklin, just north of the southern boundary. They thought themselves to be still in Utah, but the survey later showed they were in Idaho. Here they proceeded to irrigate their little ten-ac. tracts and opened the first school for whites.

The discovery of gold by Capt. E. D. Pierce in 1860 upon Orofino creek, a tributary of the Clearwater river, was more potent in the immediate fortunes of the territory. News of the rich strike started a stampede from Walla Walla in the spring of 1861. In May there were a thousand men in the new town of Pierce city, where, about Sept. 1, the officials of the first county in Idaho began functioning, though as Shoshone county of Washington territory. Lewiston was founded at the confluence of the Snake and Clearwater rivers, where the boats unloaded and the pack-trains started. Prospectors soon claimed other deposits, and Elk city and Florence became the lively centres of new districts to the south. More permanent deposits were discovered at Warren in 1862. Pack-horse trails were the only approach to some of these famous camps high in the rugged mountains.

Gold was discovered in the Boise basin of southern Idaho in 1862. By 1864 there were 16,000 people in the basin. Idaho city was the metropolis. Discoveries were also made in Owyhee county, where Ruby city and Silver city became the main camps. Silver ledges and gold-bearing quartz were found, and eastern capital was attracted by unmistakable signs of permanency. Idaho was organized as a territory in 1863, including, in addition to its present limits, also Wyoming, Montana and the portions of Nebraska, North and South Dakota west of the eastern line of Colorado continued north. William H. Wallace was ap-

pointed the first governor, and in December the first legislature met in Lewiston. In the second legislature, southern Idaho men predominated, and the capital was moved to Boise, where it has since remained. Idaho's first newspaper, the *Golden Age*, was started in Lewiston, Aug. 2, 1862, and in 1863 the publishing of the first southern Idaho newspaper, the *Boisé News*, began. In 1864 two stage lines were established from the Columbia river in the basin, and one from Salt Lake city. The telegraph did not reach Boise until 1875.

The influx of miners and ranchers on territory reserved for the Indians made the tribes restless. There were three outbreaks between 1870 and 1880. The Nez Percé chiefs refused to sign a treaty giving up fertile valleys where the whites had already settled; and when the Government tried to coerce them, they resisted. One expedition sent against them was disastrously defeated in Whitebird canyon. After a long period of skirmishing Gen. Howard met the Indians in a two days' battle near Kamiah. A charge the second day dislodged the Indians from their rifle pits, and they fled eastward over the Lo Lo trail. It was the beginning of Chief Joseph's masterly retreat of 1,300 m., which ended when he was finally captured by Gen. Miles in the Bear Paw mountains of Montana. The Bannocks, in an ugly mood after the Nez Percé war, would not stay on their reservation, and hostilities ensued. Their resistance might have been formidable had not Buffalo Horn, their able leader, been killed early in the war. This broke their spirit, and Gen. Howard easily defeated the disorganized remnants of their forces.

The first agricultural and live stock developments began in valleys near the mining districts. Such were the Boise, Payette and Weiser valleys and the valleys in the vicinity of Lewiston. Some settlers raised garden vegetables and oats and wheat, while others merely kept horse ranches, and cut the hay along the river bottoms for feed. Ranches of the latter sort became numerous along the Oregon and Montana trails. Cattle and sheep also reached Idaho over the Oregon trail, the owners of the herds settling in the fertile valleys along the route. Spanish cattle came from Utah and California. Drought in California in the years 1863, 1864 and 1871 sent large herds northward. By 1875 the ranges were well stocked, and the next year the first drove was sent east. The stock industry naturally began in the southern counties because the country was not so heavily wooded, nor was it so far from the Union Pacific railway, which was depended upon for transportation. The Oregon Short line, which was built across southern Idaho in 1882-84, greatly stimulated stock raising and general settlement. The building of the Northern Pacific across northern Idaho, 1880-82, did the same for that region. One of the wildest stampedes in the history of mining took place into this northern Coeur d'Alene country in 1884. The quartz then discovered was to make this one of the richest silver-lead regions in the world.

Farming in southern Idaho depended upon irrigation. Private enterprises in favourable localities were first resorted to, but the land that could be so irrigated was limited. Corporations were then formed to build larger canal systems. But they became so exorbitant in their demands and partial in their grants of water that the farmers hated them. Laws were passed whereby farmers themselves could control irrigation ditches. In 1894 the Carey act gave each of the States 1,000,000 ac. if the State would undertake to irrigate the land. After 1902 development under this act was rapid, and Idaho has a greater number of Carey projects than any other State. In 1902 Congress passed the Reclamation act, providing for the financing of large developments of the Federal Government. The developments in Idaho under this act are the Minidoka, King Hill and Boise projects. An important feature of the Boise project is the Arrowrock dam, 351 ft. high. The development of dry-land farming in the second decade of the present century, especially in Madison, Bonneville, Fremont, Jefferson, Bingham and Power counties, raised the income from agriculture far above that from mining, which had formerly been the most valuable industry. Despite the depression following the World War, agriculture has retained its leadership.

BIBLIOGRAPHY.—The most valuable of the biennial State reports are those of the treasurer, secretary of State, board of equalization, board of education, department of public welfare, and department of public works. The *Annual Report of the Mining Industry*, by the inspector of mines, contains extensive general and classified bibliographies of Idaho mining and geology. The bulletins and pamphlets of the Idaho bureau of mines and geology and the bulletins and circulars of the department of agriculture are excellent for their respective subjects. There is a *Manual of Horticulture* (1913) published by the State. For history and government, see H. H. Bancroft, *History of Washington, Idaho and Montana* (1890); John Hailey, *History of Idaho* (1910); W. J. McConnell, *Early History of Idaho* (1913); H. T. French, *History of Idaho* (1914); C. J. Brosnan, *History of the State of Idaho* (1918); and J. E. Rees, *Idaho Chronology* (1918), which includes a bibliography; also F. E. Lukens, *Idaho Citizen* (1925). (W. E. B.)

IDAHO FALLS, a city of E. Idaho, U.S.A., on the Snake river, 123 m. S.W. of the western entrance to Yellowstone park, at an altitude of 4,708 ft.; the county seat of Bonneville county. It is on the Oregon Short Line of the Union Pacific system, and on Federal highway 91, at the southern terminus of 191. The population was 8,064 in 1920 (90% native white), and was estimated locally at 10,752 in 1928. It is the shipping point and trading centre of a vast irrigated region of 1,250,000 ac., devoted to a variety of crops, and to stock-raising, wool-growing, dairying and cheese-making, bee-keeping and cattle and sheep-feeding. In or near the city are several large beet sugar factories (including the first one built in Idaho, in 1903), a seed-cleaning mill which supplies peas and beans for gardens from Maine to California, a factory which extracts hundreds of tons of alfalfa and sweet-clover honey, grain elevators, flour and potato-flour mills and potato and wool warehouses.

The falls are at the head of a narrow canyon. Here a toll bridge was built in 1866, and around it grew up a supply station for the freighters travelling the Utah-Montana trail. The town was long called Eagle Rock, because an eagle had a nest on a large rock in the stream just above the bridge. It was chartered as a city in 1891.

IDAR, an Indian State forming part of the Mahi Kantha agency, within the Gujarat division of Bombay. It has an area of 1,669 sq.m. and a pop. (1921) of 226,355. Much of the territory is held by kinsmen of the rajah on feudal tenure. The products are grain, oil-seeds and sugar-cane. The town of Idar, 64 m. N.E. of Ahmedabad, was formerly the capital, but the small town of Himmatnagar is the present capital. The State was created in the 18th century, by a branch of the great Rathor clan of Rajputs, to which Jodhpur and Bikaner belong. It suffered from the depredations of the Mahrattas, and still pays tribute to the gaekwar of Baroda. In 1901 the succession devolved on the famous Sir Pertab Singh, but he abdicated in 1911 to assume the regency of Jodhpur, and the present chief, Maharajah Sir Daulat Singhji, is his adopted son. The Maharajah is entitled to a salute of 15 guns.

IDAS, in Greek legend, son of Aphareus of the royal house of Messene, brother of Lynceus. In Homer (*Iliad*, ix. 556 et seq.), he is called the strongest of men on earth. He carried off Marpessa, daughter of Evenus, as his wife, and dared to bend his bow against Apollo, who was also her suitor. Zeus intervened, and left the choice to Marpessa, who declared in favour of Idas, fearing that the god might desert her when she grew old (Apollodorus i. 60-61). The Apharetidae are best known for their fight with the Dioscuri. A quarrel had arisen about the division of a herd of cattle which the four had stolen. Idas claimed the whole, and drove the cattle off to Messene. The Dioscuri overtook him and lay in wait in a hollow oak. But Lynceus, whose keenness of sight was proverbial, saw Castor through the trunk and warned his brother, who thereupon slew the mortal Castor; finally Polydeuces slew Lynceus, and Idas was struck by lightning (Apollodorus iii. 134-137; Pindar, *Nem.*, x. 60; Pausanias iv. 3. 1). According to others, the Dioscuri had carried off the daughters of Leucippus, who had been betrothed to the Apharetidae (Ovid, *Fasti*, v. 699; Theocritus xxii. 137). The scene of the combat is placed near the grave of Aphareus at Messene, at Aphidne in Attica, or in Laconia; and there are other variations of detail in the accounts (see also Hyginus, *Fab.*, 80). The grave of Idas and Lynceus was shown at Sparta, according to Pausanias

(iii. 13), whose own opinion, however, is that they were buried in Messenia.

See Roscher's *Lexikon s.v. Idas, Leukippiden, Lynkeus, Marpessa*.

IDDESLEIGH, STAFFORD HENRY NORTHCOTE, 1ST EARL OF (1818–1887), British statesman, was born in London, on Oct. 27, 1818. On leaving Balliol college, Oxford, he became in 1843 private secretary to Gladstone at the Board of Trade. He was afterwards legal secretary to the board; and after acting as one of the secretaries to the Great Exhibition of 1851, co-operated with Sir Charles Trevelyan in framing the report which revolutionized the conditions of appointment to the Civil Service. He succeeded his grandfather as 8th baronet in 1851. He entered parliament in 1855 as Conservative M.P. for Dudley, and was elected for Stamford in 1858, a seat which he exchanged in 1866 for North Devon. Steadily supporting his party, he became president of the Board of Trade in 1866, secretary of State for India in 1867, and chancellor of the exchequer in 1874. In the interval between these last two appointments he had been one of the commissioners for the settlement of the "Alabama" difficulty with the United States, and on Disraeli's elevation to the House of Lords in 1876 he became leader of the Conservative party in the Commons. As a finance minister he was largely dominated by the lines of policy laid down by Gladstone; but he distinguished himself by his dealings with the Debt, especially his introduction of the New Sinking Fund (1876), by which he fixed the annual charge for the Debt in such a way as to provide for a regular series of payments off the capital. He was transferred to the Lords in 1885, when Salisbury became prime minister. Taking the titles of earl of Iddesleigh and Viscount St. Cyres, he was included in the cabinet as first lord of the treasury. In Salisbury's 1886 ministry he was secretary of state for foreign affairs, but the arrangement was unsatisfactory, and his resignation had just been decided upon when on Jan. 12, 1887, he died very suddenly at Salisbury's official residence in Downing Street.

He wrote *Twenty Years of Financial Policy* (1862). See Andrew Lang, *Life of Lord Iddesleigh* (1890).

IDEA, a term used both popularly and in philosophical terminology with the general sense of "mental vision," (Gr. *lōēa* connected with *lōēiv*, to see). To have no *idea* how a thing happened is to be without a mental picture of an occurrence. In this general sense it is synonymous with concept (*q.v.*) in its popular usage. In philosophy the term "idea" is common to all languages and periods, but there is scarcely any term which has been used with so many different shades of meaning. Plato used it in the sphere of metaphysics for the eternally existing reality, the archetype, of which the objects of sense are more or less imperfect copies. Chairs may be of different forms, sizes, colours and so forth, but "laid up in the mind of God" there is the one permanent *idea* or type, of which the many physical chairs are derived with various degrees of imperfection. From this doctrine it follows that these *ideas* are the sole reality (see further IDEALISM); in opposition to it are the empirical thinkers of all time who find reality in particular physical objects (see HYLOZOISM, EMPIRICISM, etc.). For other meanings of the word see PSYCHOLOGY.

IDEAL means primarily that which is of the nature of an idea. It is, however, more commonly used to denote that which is perfect or supreme of its kind. See IDEA and IDEALISM.

IDEALISM, a term generally used for the attitude of mind which is prone to represent things in an imaginative light and to lay emphasis exclusively or primarily on abstract perfection (*i.e.*, on "ideals") (from Gr. *lōēa*, archetype or model, through Fr. *idéisme*). With this meaning the philosophical use of the term has little in common.

To understand the philosophical theory that has come to be known under this title, we may ask (1) what in general it is and how it is differentiated from other theories of knowledge and reality, (2) how it has risen in the history of philosophy, (3) what position it occupies at the present time in the world of speculation.

General Definition of Idealism.—Idealism as a philosophical doctrine conceives of knowledge or experience as a process in

which the two factors of subject and object stand in a relation of entire interdependence on each other as warp and woof. Apart from the activity of the self or subject in sensory reaction, memory and association, imagination, judgment and inference, there can be no world of objects. A thing-in-itself which is not a thing to some consciousness is an entirely unrealizable, because self-contradictory, conception. But this is only one side. It is equally true that a subject apart from an object is unintelligible. As the object exists for knowledge through the constructive activity of the subject, so the subject lives in the construction of the object. To seek for the true self in any region into which its opposite in the form of a not-self does not enter is to grasp a shadow. It is in seeking to realize its own ideas in the world of knowledge, feeling and action that the mind comes into possession of itself; it is in becoming permeated and transformed by the mind's ideas that the world develops for us the fullness of its reality as object.

Thus defined, idealism is opposed to ordinary common-sense dualism, which regards knowledge or experience as the result of the more or less accidental relation between two separate and independent entities—the mind and its ideas on one side, the thing with its attributes on the other—that serve to limit and condition each other from without. It is equally opposed to the doctrine which represents the subject itself and its states and judgments as the single immediate datum of consciousness, and all else, whether objects in an external world or persons other than the individual subject whose states are known to itself, as having a merely problematic existence resting upon analogy or other process of indirect inference. This theory is sometimes known as idealism. But it falls short of idealism as above defined in that it recognizes only one side of the antithesis of subject and object, and so falls short of the doctrine which takes its stand on the complete correlativity of the two factors in experience. It is for this reason that it is sometimes known as subjective or incomplete idealism. Finally the theory defined is opposed to all forms of realism, whether in the older form which sought to reduce mind to a function of matter, or in any of the newer forms which seek for the ultimate essence of both mind and matter in some unknown force or energy which, while in itself it is neither, yet contains the potentiality of both. It is true that in some modern developments of idealism the ultimate reality is conceived of in an impersonal way, but it is usually added that this ultimate or absolute being is not something lower but higher than self-conscious personality, including it as a more fully developed form may be said to include a more elementary.

Origin and Development of Idealism.—In its self-conscious form idealism is a modern doctrine. In it the self or subject may be said to have come to its rights. This was possible in any complete sense only after the introspective movement represented by the middle ages had done its work, and the thought of the individual mind and will as possessed of relative independence had worked itself out into some degree of clearness. In this respect Descartes' dictum—*cogito ergo sum*—may be said to have struck the keynote of modern philosophy, and all subsequent speculation to have been merely a prolonged commentary upon it. While in its completer form it is thus a doctrine distinctive of modern times, idealism has its roots far back in the history of thought. One of the chief proofs that has been urged of the truth of its point of view is the persistency with which it has always asserted itself at a certain stage in philosophical reflection and as the solution of certain recurrent speculative difficulties. All thought starts from the ordinary dualism or pluralism which conceives of the world as consisting of the juxtaposition of mutually independent things and persons. The first movement is in the direction of dispelling this appearance of independence. They are seen to be united under the relation of cause and effect, as attributes of an underlying substance, or again as temporal manifestations of some single entity or energy which constitutes the eternal essence of the things that come before our knowledge. But in the pantheism that thus takes the place of the old dualism there seems no permanent place left for the individual. Mind and will in their individual manifestations fade into the general background without significance except as a link in a necessary

chain. Deliverance from the pantheistic conception of the universe was sought in the recognition of the central place occupied by thought and purpose in the actual world, and as a consequence of this, of the illegitimacy of the abstraction whereby material energy is taken for the ultimate reality.

Ancient Idealism: Socrates and Plato.—The first illustration of this movement on a large scale was given in the Socratic reaction against the pantheistic conclusions of early Greek philosophy (see IONIAN SCHOOL). The whole movement of which Socrates was a part may be said to have been in the direction of the assertion of the rights of the subject. Its keynote is to be found in the principle "man is the measure." This was interpreted by its author, Protagoras, and by the Sophists in general in a subjective sense, with the result that it became the motto of a sceptical and individualistic movement in contemporary philosophy and ethics. It was not less against this form of idealism than against the determinism of the early physicists that Socrates protested. Along two lines the thought of Socrates led to idealistic conclusions which may be said to have formed the basis of all subsequent advance. (1) He perceived the importance of the universal or conceptual element in knowledge, and thus at a single stroke broke through the hard realism of ordinary common sense, disproved all forms of naturalism that were founded on the denial of the reality of concepts, and cut away the ground from a merely sensational and subjective idealism. This is what Aristotle means by claiming for Socrates that he was the founder of definition. (2) He taught that life was explicable only as a system of ends. Goodness consists in the knowledge of what these are. It is by his hold upon them that the individual is able to give unity and reality to his will. In expounding these ideas Socrates limited himself to the sphere of practice. Moreover, the end or ideal of the practical life was conceived of in too vague a way to be of much practical use. His principle, however, was essentially sound, and led directly to the Platonic Idealism.

Plato extended the Socratic discovery to the whole of reality and while seeking to see the pre-Socratics with the eyes of Socrates sought "to see Socrates with the eyes of the pre-Socratics." Not only were the virtues to be explained by their relation to a common or universal good which only intelligence could apprehend, but there was nothing in all the furniture of heaven or earth which in like manner did not receive reality from the share it had in such an intelligible idea or essence. But these ideas are themselves intelligible only in relation to one another and to the whole. Accordingly Plato conceived of them as forming a system and finding their reality in the degree in which they embody the one all-embracing idea, conceived of not under the form of an efficient but of a final cause, an inner principle of action or tendency in things to realize the fullness of their own nature which in the last resort was identical with the nature of the whole. This Plato expressed in the myth of the Sun, but the garment of mythology in which Plato clothed his idealism, beautiful as it is in itself and full of suggestion, covered an essential weakness. The more Plato dwelt upon his world of ideas, the more they seemed to recede from the world of reality, standing over against it as principles of condemnation instead of revealing themselves in it. In this way the Good was made to appear as an end imposed upon things from without by a creative intelligence instead of as an inner principle of adaptation.

Aristotle.—On one side of his thought Aristotle represents a reaction against idealism and a return to the position of common-sense dualism, but on another, and this the deeper side, he represents the attempt to restore the theory in a more satisfactory form. His account of the process of knowledge in his logical treatises exhibits the idealistic bent in his philosophy. This is as far removed as possible either from dualism or from empiricism. The universal is the real; it is that which gives coherence and individuality to the particulars of sense which apart from it are like the routed or disbanded units of an army. Still more manifestly in his *Ethics* and *Politics* Aristotle makes it clear that it is the common or universal will that gives substance and reality to the individual. In spite of these and other anticipations of a fuller idealism, the idea remains as a form imposed from without on a

reality otherwise conceived of as independent of it. As we advance from the logic to the metaphysics and from that to his ontology, it becomes clear that the concepts are only "categories" or predicates of a reality lying outside of them, and there is an ultimate division between the world as the object or matter of thought and the thinking or moving principle which gives it life. It is this that gives the Aristotelian doctrine in its more abstract statements an air of uncertainty. Yet besides the particular contribution that Aristotle made to idealistic philosophy in his logical and ethical interpretations, he advanced the case in two directions: (a) He made it clear that no explanation of the world could be satisfactory that was not based on the notion of continuity in the sense of an order of existence in which the reality of the lower was to be sought for in the extent to which it gave expression to the potentialities of its own nature—which were also the potentialities of the whole of which it was a part. (b) From this it followed that, difficult as we might find it to explain the relation of terms so remote from each other as sense and thought, the particular and the universal, matter and mind, these oppositions cannot in their nature be absolute. These truths, however, were hidden from Aristotle's successors, who for the most part lost the thread which Socrates had put into their hand. When the authority of Aristotle was again invoked, it was its dualistic and formal, not its idealistic and metaphysical, side that was in harmony with the spirit of the age. Apart from one or two of the greatest minds, notably Dante, what appealed to the thinkers of the middle ages was not the idea of reality as a progressive self-revelation of an inner principle working through nature and human life, but the formal principles of classification which it seemed to offer for a material of thought and action accepted from another source.

Modern Idealism.—Modern like ancient idealism came into being as a correction of the view that threatened to resolve the world of matter and mind alike into the changing manifestations of some single non-spiritual force or substance. While, however, ancient philosophy may be said to have been unilinear, modern philosophy had a twofold origin, and till the time of Kant may be said to have pursued two independent courses.

Cartesianism.—All philosophy is the search for reality and rational certainty as opposed to mere formalism on the one hand, to authority and dogmatism on the other. In this sense modern philosophy had a common root in revolt against mediaevalism. In England this revolt sought for the certainty and clearness that reason requires in the assurance of an outer world given to immediate sense experience; on the continent of Europe, in the assurance of an inner world given immediately in thought. Though starting from apparently opposite poles and following widely different courses the two movements led more or less directly to the same results. It is easy to understand how English sensationism issued at once in the trenchant naturalism of Hobbes. It is less comprehensible how the Cartesian philosophy from the starting-point of thought allied itself with a similar point of view. This can be understood only by a study of the details of Descartes' philosophy. Suffice it to say that in spite of its spiritualistic starting-point its general result was to give a stimulus to the prevailing scientific tendency as represented by Galileo, Kepler and Harvey to the principle of mechanical explanations of the phenomena of the universe. True it was precisely against this that Descartes' immediate successors struggled. But the time-spirit was too strong for them. Determinism had other forms besides that of a crude materialism, and the direction that Malebranche succeeded in giving to speculation led to Spinoza's pantheism.

Berkeley.—The foundations of idealism in the modern sense were laid by the thinkers who sought breathing room for mind and will in a deeper analysis of the relations of the subject to the world that it knows. From the outset English philosophy had a leaning to the psychological point of view, and Locke was only carrying on the tradition of his predecessors and particularly of Hobbes in definitely accepting it as the basis of his *Essay*. It was, however, Berkeley who first sought to utilize the conclusions that were implicit in Locke's starting-point. Berkeley's statement of the view that all knowledge is relative to the subject—that no object can be known except under the form which our powers of

sense-perception, our memory and imagination, our notions and inference, give it—is still the most striking that we possess. To have established this position was a great step in speculation. Henceforth ordinary dogmatic dualism was excluded from philosophy; any attempt to revive it, whether with Dr. Johnson by an appeal to common prejudice, or in the more reflective Johnsonianism of the 18th-century Scottish philosophers, must be an anachronism. Equally impossible was it thenceforth to assert the mediate or immediate certainty of material substance as the cause either of events in nature or of sensations in ourselves. But with these advances came the danger of falling into error from which common-sense dualism and naturalistic monism were free. From the point of view which Berkeley had inherited from Locke it seemed to follow that not only material substance, but the whole conception of a world of objects, is at most an inference from subjective modifications which are the only immediately certain objects of knowledge. The implications of such a view were first clearly apparent when Hume showed that on the basis of it there seemed to be nothing that we could confidently affirm except the order of our own impressions and ideas. This being so, not only were physics and mathematics impossible as sciences of necessary objective truth, but our apparent consciousness of a permanent self and object alike must be delusive.

Kant and Leibniz.—It was these paradoxes that Kant sought to rebut by a more thoroughgoing criticism of the basis of knowledge the substance of which is summed up in his celebrated *Refutation of Idealism*, wherein he sought to undermine Hume's scepticism by carrying it one step further and demonstrating that not only is all knowledge of self or object excluded, but the consciousness of any series of impressions and ideas is itself impossible except in relation to some external permanent and universally accepted world of objects.

But Kant's refutation of subjective idealism and his vindication of the place of the object can be fully understood only when we take into account the other defect in the teaching of his predecessors that he sought in his *Critique* to correct. In continental philosophy the reaction against mechanical and pantheistic explanations of the universe found even more definite utterance than in English psychological empiricism in the metaphysical system of Leibniz, whose theory of self-determined monads can be understood only when taken in the light of the assertion of the rights of the subject against the Substance of Spinoza and the atoms of the materialist. But Leibniz also anticipated Kant in seeking to correct the empirical point of view of the English philosophers. True, sense-given material is necessary in order that we may have thought. "But by what means," he asks, "can experience and the senses give ideas? Has the soul windows? Is it like a writing tablet? Is it like wax? It is plain that all those who think thus of the soul make it at bottom corporeal. True, nothing is in the intellect which has not been in the senses, but we must add except the intellect itself. The soul contains the notions of being, substance, unity, identity, cause, perception, reasoning and many others which the senses cannot give" (*Nouveaux essais*, ii. 1). But Leibniz's conception of the priority of spirit had too little foundation, and the different elements he sought to combine were too loosely related to one another to stand the strain of the two forces of empiricism and materialism that were opposed to his idealism. More particularly by the confusion in which he left the relation between the two logical principles of identity and of sufficient reason underlying respectively analytic and synthetic, deductive and inductive thought, he may be said to have undermined in another way the idealism he strove to establish. It was in seeking to close up the fissure in his system represented by this dualism that his successors succeeded only in adding weakness to weakness by reducing the principle of sufficient reason to that of formal identity (see WOLFF) and representing all thought as in essence analytic. From this it immediately followed that, so far as the connection of our experiences of the external world does not show itself irreducible to that of formal identity, it must remain unintelligible. As empiricism had foundered on the difficulty of showing how our thoughts could be an object of sense experience, so Leibnizian formalism foundered on that of understanding how

the material of sense could be an object of thought. On one view as on the other scientific demonstration was impossible.

The extremity to which philosophy had been brought by empiricism on the one hand and formalism on the other was Kant's opportunity. Leibniz's principle of the "nisi intellectus ipse" was expanded by him into a demonstration the completest yet effected by philosophy of the part played by thought not merely in the manipulation of the material of experience but in the actual constitution of the object that is known. On the other hand he insisted on the objective reference of this activity without which it was impossible to get beyond the circle of our own thoughts. The parts of the *Critique of Pure Reason*, more particularly the "Deduction of the Categories" in which this theory is worked out, may be said to have laid the foundation of modern idealism—"articulum stantis aut cadentis doctrinae." In spite of the defects of Kant's statement—to which it is necessary to return—the place of the concepts and ideals of the mind and the synthetic organizing activity which these involve was established with a trenchancy which has been acknowledged by all schools alike. The "Copernican revolution" which he claimed to have effected may be said to have become the starting-point of all modern philosophy. Yet the divergent uses that have been made of it witness to the ambiguity of his statement which is traceable to the fact that Kant was himself too deeply rooted in the thought of his predecessors and carried with him too much of their spirit to be able entirely to free himself from their assumptions and abstractions. His philosophy was more like Michaelangelo's famous sculpture of the Dawn, a spirit yet encumbered with the stubble of the material from which it was hewn, than a clear cut figure with unmistakable outlines. Chief among these encumbering presuppositions was that of a fundamental distinction between perception and conception and consequent upon it between the synthetic and the analytic use of thought. It is upon this in the last resort that the distinction between the phenomenal world of our experience and a noumenal world beyond it is founded. Kant perceives that "perception without conception is blind, conception without perception is empty," but if he goes so far ought he not to have gone still further and inquired whether there can be any perception at all without a concept, any concept which does not presuppose a precept, and, if this is impossible, whether the distinction between a world of appearance which is known and a world of things-in-themselves which is not, is not illusory?

Hegel.—It was by asking precisely these questions that Hegel gave the finishing strokes to the Kantian philosophy. The starting-point of all valid philosophy must be the perception that the essence of all conscious apprehension is the union of opposites—of which that of subject and object is the most fundamental and all-pervasive. True, before differences can be united they must have been separated, but this merely proves that differentiation or analysis is only one factor in a single process. Equally fundamental is the element of synthesis. Nor is it possible at any point in knowledge to prove the existence of a merely given object in whose determination the thinking subject has played no part, nor a merely thinking subject in whose structure the object is not an organic factor. In coming, as at a certain point in its development it does, to the consciousness of an object, the mind does not find itself in the presence of an opponent, or of anything essentially alien to itself but of that which gives content and stability to its own existence. True, the stability it seems thus to find is incomplete. The mind cannot rest in the immediate appearance of the object without involving us in contradiction. The sun does not "rise," the dew does not "fall." But this only means that the unity between subject and object to which the gift of consciousness commits us is incompletely realized in that appearance: the apparent truth has to submit to correction and supplementation before it can be accepted as real truth. It does not mean that there is anywhere a mere fact which is not also an interpretation, nor an interpreting mind whose ideas have no hold upon fact. From this it follows that ultimate or absolute reality is to be sought not beyond the region of experience, but in the fullest and most harmonious statement of the facts of our experience. True a com-

pletely harmonious world whether of theory or of practice remains an ideal. But the fact that we have already in part realized the ideal and that the degree in which we have realized it is the degree in which we may regard our experience as trustworthy, is proof that the ideal is no mere idea as Kant taught, but the very substance of reality.

Intelligible as this development of Kantian idealism seems in the light of subsequent philosophy, the first statement of it in Hegel was not free from obscurity. The unity of opposites translated into its most abstract terms as the "identity of being and not-being," the principle that the "real is the rational," the apparent substitution of "bloodless" categories for the substance of concrete reality gave it an air of paradox in the eyes of metaphysicians, while physicists were scandalized by the premature attempts at a complete philosophy of nature and history. For this Hegel was doubtless partly to blame. But philosophical critics of his own and a later day are not hereby absolved from a certain perversity in interpreting these doctrines in a sense precisely opposite to that in which they were intended. The doctrine of the unity of contraries so far from being the denial of the law of non-contradiction is founded on an absolute reliance upon it. Freed from paradox it means that in every object of thought there are different aspects or elements each of which if brought separately into consciousness may be so emphasized as to appear to contradict another. Unity may be made to contradict diversity, permanence change, the particular the universal, individuality relatedness. Ordinary consciousness ignores these "latent fires"; ordinary discussion brings them to light and divides men into factions and parties over them; philosophy not because it denies but because it acknowledges the law of non-contradiction as supreme is pledged to seek a point of view from which they may be seen to be in essential harmony with one another as different sides of the same truth. The "rationality of the real" has in like manner been interpreted as intended to sanctify the existing order. Hegel undoubtedly meant to affirm that the actual was rational in the face of the philosophy which set up subjective feeling and reason against it. But idealism has insisted from the time of Plato on the distinction between what is actual in time and space and the reality that can only partially be revealed in it. Hegel carried this principle further than had yet been done. His phrase does not therefore sanctify the established fact but, on the contrary, declares that it partakes of reality only so far as it embodies the ideal of a coherent and stable system which it is not. As little is idealism responsible for any attempt to pass off logical abstractions for concrete reality. The "Logic" of Hegel is merely the continuation of Kant's "Deduction" of the categories and ideas of the reason which has generally been recognized as the soberest of attempts to set forth the presuppositions which underlie all experience. "What Hegel attempts to show is just that the categories by which thought must determine its object are stages in a process that, beginning with the idea of 'Being,' the simplest of all determinations is driven on by its own dialectic till it reaches the idea of self-consciousness. In other words the intelligence when it once begins to define an object for itself, finds itself launched on a movement of self-asserting synthesis in which it cannot stop until it has recognized that the unity of the object with itself involves its unity with all other objects and with the mind that knows it. Hence, whatever we begin by saying, we must ultimately say 'mind'" (Caird, *Kant*, i. 443).

Idealism in England and America.—While the form in which these doctrines were stated proved fatal to them in the country of their birth, they took deep root in the next generation in English philosophy. Here the stone that the builders rejected was made the head of the corner. The influences which led to this result were manifold. From the side of literature the way was prepared for it by the genius of Coleridge, Wordsworth and Carlyle; from the side of morals and politics by the profound discontent of the constructive spirit of the century with the disintegrating conceptions inherited from utilitarianism. In taking root in England idealism had to contend against the traditional empiricism represented by Mill on the one hand and the pseudo-Kantianism which was rendered current by Mansel and Hamilton

on the other. As contrasted with the first it stood for the necessity of recognizing a universal or ideal element as a constitutive factor in all experience whether cognitive or volitional; as contrasted with the latter for the ultimate unity of subject and object, knowledge and reality, and therefore for the denial of the existence of any thing-in-itself for ever outside the range of experience. Its polemic against the philosophy of experience has exposed it to general misunderstanding, as though it claimed some *a priori* path to truth. In reality it stands for a more thoroughgoing and consistent application of the test of experience. The defect of English empiricism from the outset had been the uncritical acceptance of the metaphysical dogma of a pure unadulterated sense-experience as the criterion of truth. This assumption idealism examines and rejects in the name of experience itself. Similarly it only carried the doctrine of relativity to its logical conclusion in denying that there could be any absolute relativity. Object stands in essential relation to subject, subject to object. This being so, it is wholly illogical to seek for any test of the truth and reality of either except in the form which that relation itself takes. In its subsequent development idealism in England has passed through several clearly marked stages which may be distinguished as (a) that of exploration and tentative exposition in the writings of J. F. Ferrier, J. Hutchison Stirling, Benjamin Jowett, W. T. Harris; (b) of confident application to the central problems of logic, ethics and politics, fine art and religion, and as a principle of constructive criticism and interpretation chiefly in T. H. Green, E. Caird, B. Bosanquet; (c) of vigorous effort to develop on fresh lines its underlying metaphysics in F. H. Bradley, J. M. E. McTaggart, A. E. Taylor, Josiah Royce and others. Under the influence of these writers idealism, as above expounded though with difference of interpretation in individual writers, may be said towards the end of the 19th century to have been on its way to becoming the leading philosophy in the British Isles and America.

Reaction against Traditional Idealism.—But it was not to be expected that the position idealism had thus won for itself would remain long unchallenged. It had its roots in a literature and in forms of thought remote from the common track; it had been formulated before the great advances in psychology which marked the course of the century; its latest word seemed to involve consequences that brought it into conflict with the vital interest the human mind has in freedom and the possibility of real initiation. It is not, therefore, surprising that there should have been a vigorous reaction. This has taken mainly two opposite forms. On the one hand the attack has come from the old ground of the danger that is threatened to the reality of the external world and may be said to be in the interest of the object. On the other hand the theory has been attacked in the interest of the subject on the ground that in the statuesque world of ideas into which it introduces us it leaves no room for the element of movement and process which recent psychology and metaphysic alike have taught us underlies all life. The conflict of idealism with these two lines of criticism—the accusation of subjectivism on the one side, of intellectualism and rigid objectivism on the other—may be said to have constituted the history of Anglo-Saxon philosophy during the first two decades of the 20th century.

New Dualism.—Whatever is to be said of ancient Idealism, the modern doctrine may be said notably in Kant to have been in the main a vindication of the subjective factor in knowledge. But that space and time, matter and cause should owe their origin to the action of the mind has always seemed paradoxical to common sense. Nor is the impression which its enunciation in Kant made, likely to have been lightened in this country by the connection that was sure to be traced between Berkeleyanism and the new teaching or by the form which the doctrine received at the hands of T. H. Green, its leading English representative between 1870 and 1880. If what is real in things is ultimately nothing but their relations, and if relations are inconceivable apart from the relating mind, what is this but the dissolution of the solid ground of external reality which my consciousness seems to assure me underlies and eludes all the conceptual network by which I try to bring one part of my experience into connection with another? It is quite true that modern idealists like Berkeley himself have

sought to save themselves from the gulf of subjectivism by calling in the aid of a universal or infinite mind or by an appeal to a total or absolute experience to which our own is relative. But the former device is too obviously a *deus ex machina*, the purpose of which would be equally well served by supposing with Fichte the individual self to be endowed with the power of subconsciously extraditing a world which returns to it in consciousness under the form of a foreign creation. The appeal to an Absolute on the other hand is only to substitute one difficulty for another. For granting that it places the centre of reality beyond the individual self it does so only at the price of reducing the reality of the latter to an appearance; and if only one thing is real what becomes of the many different things which again my consciousness assures me are the one world with which I can have any practical concern? To meet these difficulties and give back to us the assurance of the substantiality of the world without us it has therefore been thought necessary to maintain two propositions which are taken to be the refutation of idealism. (1) There is given to us immediately in knowledge a world entirely independent of and different from our own impressions on the one hand and the conceptions by which we seek to establish relations between them upon the other. The relation of these impressions (and for the matter of that their inter-relations among themselves) to our minds is only one out of many. As a leading writer puts it: "There is such a thing as greenness having various relations, among others that of being perceived." (*Mind*, N. S. xii. p. 433.) (2) Things may be, and may be known to be simply different. They may exclude one another, exist so to speak in a condition of armed neutrality to one another, without being positively thereby related to one another or altered by any change taking place in any of them. As the same writer puts it: "There is such a thing as numerical difference, different from conceptual difference," or expressing the same thing in other words "there are relations not grounded in the nature of the related terms." (*Proc. Arist. Soc.*, 1901, p. 110.)

In this double-barrelled criticism it is important to distinguish what is really relevant. Modern idealism differs from the arrested idealism of Berkeley precisely in the point on which dualism insists. In all knowledge we are in touch not merely with the self and its passing states, but with a real object which is different from them. On this head there is no difference, and idealism need have no difficulty in accepting all that its opponents here contend. The difference between the two theories does not consist in any difference of emphasis on the objective side of knowledge, but in the standard by which the reality of the object is to be tested—the difference is logical not metaphysical—it concerns the definition of truth or falsity in the knowledge of the reality which both admit. To idealism there can be no ultimate test, but the possibility of giving any fact which claims to be true its place in a coherent system of mutually related truths. To this dualism opposes the doctrine that truth and falsehood are a matter of mere immediate intuition: "There is no problem at all in truth and falsehood, some propositions are true and some false just as some roses are red and some white." (*Mind*, N. S. xiii. p. 523.)

Pragmatism.—More widespread and of more serious import is the attack to which idealism has been subjected from the side of the subject and subjective interests which has found expression in Pragmatism and kindred movements. Here also it is important to distinguish what is relevant from what is irrelevant in the line of criticism represented by these writers. There need be no contradiction between idealism and a reasonable pragmatism. In so far as the older doctrine is open to the charge of neglecting the conative and teleological side of experience it can afford to be grateful to its critics for recalling it to its own eponymous principle of the priority of the "ideal" to the "idea," of *needs* to the conception of their object. The real issue comes into view in the attempt, undertaken in the interest of freedom, to substitute for the notion of the world as a cosmos (with a permanent, resistant structure) one of it as only so far cosmic as to be capable of being infinitely moulded to human desire.

To the older idealism as to the new the essence of mind or spirit is freedom. But the guarantee of freedom is to be sought for not in the denial of law, but in the whole nature of mind and

its relation to the structure of experience. *Without mind no orderly world*: only through the action of the subject and its "ideas" are the confused and incoherent data of sense-perception (themselves shot through with both strands) built up into that system of things which we call Nature, and which stands out against the subject as the body stands out against the soul whose functioning may be said to have created it. On the other hand, *without the world no mind*: only through the action of the environment upon the subject is the idealizing activity in which it finds its being called into existence. Herein lies the paradox which is also the deepest truth of our spiritual life. In interpreting its environment first as a world of things that seem to stand in a relation of exclusion to one another and to itself, then as a natural system governed by rigid mechanical necessity, the mind can yet feel that in its very opposition the world is akin to it, bone of its bone and flesh of its flesh. What is true of mind is true of will. Idealism starts from the relativity of the world to purposive consciousness. But this again may be so stated as to represent only one side of the truth. It is equally true that the will is relative to the world of objects and interests to which it is attached through instincts and feelings, habits and sentiments. In isolation from its object the will is as much an abstraction as thought apart from the world of percepts, memories and associations which give it content and stability. And just as mind does not lose but gains in individuality in proportion as it parts with any claim to the capricious determination of what its world shall be, and becomes dominated by the conception of an order which is immutable, so the will becomes free and "personal" in proportion as it identifies itself with objects and interests, and subordinates itself to laws and requirements, which involve the suppression of all that is merely arbitrary and subjective. Here, too, subject and object grow together. The power and vitality of the one is the power and vitality of the other, and this is so because they are not two things with separate roots but are both rooted in a common reality which, while it includes both is more than either.

Seeing nothing but irreconcilable contradiction between the conceptions of the world as immutable law and a self-determining subject the new idealism seeks other means of vindicating the reality of freedom. It agrees with older forms of libertarianism in taking its stand on the fact of spontaneity as primary and self-evidencing, but it is not content to assert its existence side by side with rigidly determined sequence. It carries the war into the camp of the enemy by seeking to demonstrate that the completely determined action which is set over against freedom as the basis of explanation in the material world is merely a hypothesis which, while it serves sufficiently well the limited purpose for which it is devised, is incapable of verification in the ultimate constituents of physical nature. There seems in fact nothing to prevent us from holding that while natural laws express the average tendencies of multitudes they give no clue to the movement of individuals. Some have gone farther and argued that from the nature of the case no causal explanation of any real change in the world of things is possible. A cause is that which contains the effect, but this is precisely what can never be proved with respect to anything that is claimed as a real cause in the concrete world. Everywhere the effect reveals an element which is undiscoverable in the cause with the result that the identity we seek for ever eludes us. Even the resultant of mechanical forces refuses to resolve itself into its constituents. In the "resultant" there is a new direction, and with it a new quality the component forces of which no analysis can discover.

It is not here possible to do more than indicate what appear to be the valid elements in these two conflicting interpretations of the requirements of a true idealism. On behalf of the older it may be affirmed that no solution is likely to find acceptance which involves the rejection of unity and intelligible order as the primary principle of our world. The assertion of this principle by Kant was the corner-stone of idealistic philosophy in general, underlying as it does the conception of a permanent subject not less than that of a permanent object. As little from the side of logic is it likely that any theory will find acceptance which reduces all thought to a process of analysis and the discovery of

abstract identity. There is no logical principle which requires that we should derive qualitative change by logical analysis from quantitative difference. Everywhere experience is synthetic: it gives us multiplicity in unity. Explanation does not require the annihilation of all differences but the apprehension of them as in organic relation to one another and to the whole to which they belong. The revival as in the above argument of the idea that the function of thought is the elimination of difference, and that rational connection must fail where absolute identity is indiscoverable merely shows how imperfectly Kant's lesson has been learned by some of those who prophesy in his name. Apart from the narrowness which would limit human interest to "practice," as pragmatism fain would do, there is paradox in a theory which, at a moment when the best inspiration in poetry, sociology and physical science comes from the idea of the unity of the world, gives in its adhesion to an irrational pluralism on the ground of its preponderating practical value.

On the other hand, idealism would be false to itself if it interpreted the unity which it thus seeks to establish in any sense that is incompatible with the validity of moral distinctions and human responsibility in the fullest sense of the term. It would on its side be, indeed, a paradox if at a time when the validity of human ideals and the responsibility of nations and individuals to realize them is more universally recognized than ever before on our planet, the philosophical theory which hitherto has been chiefly identified with their vindication should be turned against them. Perhaps the depth and extent of the dissatisfaction are sufficient evidence that most recent developments are not free from ambiguity on this vital issue. But what is thus suggested is not a rash departure from the general point of view of idealism, but a cautious inquiry into the possibility of reaching a conception of the world in which a place can be found at once for the idea of unity and determination and of movement and freedom.

IDELER, CHRISTIAN LUDWIG (1766-1846), German chronologist and astronomer, was born near Perleberg on Sept. 21, 1766. He became professor at the university of Berlin in 1821, and 18 years later foreign member of the Institute of France. From 1816 to 1822 he was tutor to the young princes William Frederick and Charles. He died in Berlin on Aug. 10, 1846. He devoted his life chiefly to the examination of ancient systems of chronology. In 1825-26 he published his great work, *Handbuch der mathematischen und technischen Chronologie* (2 vols.; 2nd ed., 1883), re-edited as *Lehrbuch der Chronologie* (1831); a supplementary volume, *Die Zeitrechnung der Chinesen*, appeared in 1839.

IDENTIFICATION: see FINGER-PRINTS, EVIDENCE, INVESTIGATION: *Criminal*.

IDENTITY PHILOSOPHY is a system of philosophy which treats mind and matter, subject and object or thought and existence, as merely two aspects or expressions of the same ultimate reality (or underlying identity). There are many systems of philosophy which answer more or less to this general description, though different in other respects. Indeed some of them are on the verge of idealism, and some are on the verge of materialism. The most familiar instances of Identity Philosophies, ancient and modern, are the systems of the Eleatics, Spinoza, Fichte, Schelling and Hegel.

See BODY AND MIND, ONTOLOGY and the articles on the philosophers named above.

IDENTITY, PRINCIPLE OF. Identity means sameness, and a thing can only be the same as itself. Two or more things may be very similar to each other; they cannot be the same as each other, except in the sense of "extremely similar to one another"—

a sense in which "same" and "identical" are sometimes used. In a statement of the type "*S* is identical with *P*," *S* and *P* can only be two names of one and the same object. In all consistent thought and discourse it is assumed that the object of thought has a certain definite character which it retains more or less. This assumption is one of the so-called Laws of Thought. It is known as the Postulate or Principle of Identity, and is frequently expressed in the formula *A is A*. This assumption may appear to conflict with the obvious changes in the objects of daily experience. But *change* implies *identity*. A thing is not said to change when something else is substituted for it. Change implies a certain continuity or identity of the old with the new. In some cases indeed absence of change might be strong evidence *against* identity. If I meet a youth who looks exactly like my school-fellow looked forty years ago, I am quite sure it is a different person, though possibly closely related to him. In calling the Principle of Identity an assumption or postulate it is not intended to suggest that it is *merely* an intellectual assumption; it is believed to be true of things, even if this cannot be proved to be the case. See THOUGHT, LAWS OF. For identity in logic see EXPLANATION, and for identity in mathematics see EQUATIONS, THEORY OF.

See also H. W. B. Joseph, *Introduction to Logic* (1916); J. S. Mackenzie, *Elements of Constructive Philosophy* (1917).

IDEOGRAPH, a symbol or character painted, written or inscribed, representing ideas, not sounds; it occurs in Chinese and in most Egyptian hieroglyphs (Gr. *idéa*, idea and *γράφειν*, to write). (See WRITING.)

IDES. The name given in the Roman calendar to the 13th day of the month with the exception of March, May, July and October, the Ides in these months falling on the 15th day. See CALENDAR.

IDIOBLAST, a botanical term for an individual cell which is distinguished by its shape, size or contents, such as the stone-cells in the soft tissue of a pear.

IDIOCY: see INSANITY.

IDIOM, a form of expression in words, grammatical construction, phraseology, etc., which is peculiar to a language; sometimes also a variety of a particular language, a dialect (Gr. *ἰδιωμα*, something peculiar and personal).

IDIOSYNCRASY, a physical or mental condition peculiar to an individual, usually taking the form of a special susceptibility to particular stimuli; thus it is an idiosyncrasy of one individual that abnormal sensations of discomfort should be excited by certain odours or colours, by the presence in the room of a cat, etc.; similarly, certain persons are found to be peculiarly responsive or irresponsive to the action of particular drugs. The word is also used, generally, of any eccentricity or peculiarity of character, appearance, etc.

IDOCRASE, a rock-forming mineral of complex composition. It is a basic calcium and aluminium silicate containing small amounts of iron, magnesium, water, fluorine, etc., and sometimes boron; the approximate formula is $H_2Ca_6(Al,Fe)_8Si_8O_{40}$. It crystallizes in the tetragonal system, but often exhibits optical anomalies, and the optical sign varies from positive to negative. Well-developed crystals are of frequent occurrence. They usually have the form of four- or eight-sided prisms terminated by the basal planes and pyramid-planes. Crystals are transparent to translucent, vitreous in lustre and vary in colour from brown to green; a sky-blue variety, called *cyprine*, owes its colour to the presence of a trace of copper. The specific gravity is 3.4 and the hardness 6½. The name vesuvianite is also in common use for this mineral.

Idocrase is typically a mineral of contact-metamorphic origin, occurring most frequently in crystalline limestones at their contact with igneous rock-masses; it also occurs in serpentine, chlorite-schist and gneiss, and is usually associated with garnet, diopside, wollastonite, etc. Localities which have yielded fine crystallized specimens are the Ala valley in Piedmont, Monte Somma (Vesuvius), the River Wilui in Siberia ("wiluite"), Christiansand in Norway, etc. When found as transparent crystals of a good green or brown colour it is occasionally cut as a gem-stone. A compact variety ("californite"), closely resembling jade in appear-

ance, has been used as an ornamental stone.

IDOL, in philosophy, means a prejudice of some kind which is a hindrance to objective, impartial or free thought. The term was first used in this sense by Giordano Bruno and adopted from him by Francis Bacon, who is chiefly responsible for the vogue which it has. Bacon distinguished four kinds of idols, namely: (1) *idols of the tribe*, prejudices more or less common to the whole human race; (2) *idols of the cave*, prejudices peculiar to individuals; (3) *idols of the market place*, prejudices encouraged by one's social group and mother tongue; (4) *idols of the theatre*, or prejudices or false notions taught and encouraged by various schools of thought.

See F. Bacon, *Novum Organum*.

IDOLATRY, the worship of idols, *i.e.*, images or other objects believed to represent or be the abode of a superhuman personality. The term is often used generically to include such varied forms as litholatry, dendrolatry, pyrolatry, zoolatry and even necrolatry. In an age when the study of religion was practically confined to Judaism and Christianity, idolatry was regarded as a degeneration from an uncorrupt primeval faith, but the comparative and historical investigation of religion has shown it to be rather a stage of an upward movement, and that by no means the earliest.

As the earlier stages in the development of the religious consciousness persist and are often manifest in idolatry, so in the higher stages, when men have attained loftier spiritual ideas, idolatry itself survives and is abundantly visible as a reactionary tendency. The history of the Jewish people whom the prophets sought, for long in vain, to wean from worshipping images is an illustration; so, too, the vulgarities of modern popular Hinduism contrasted with the lofty teaching of the Indian sacred books.

In the New Testament the word *εἰδωλατρεία* (*idololatria*), afterwards shortened occasionally to *εἰδωλατρία* (*idolatria*), occurs in all four times, viz., in 1 Cor. x. 14; Gal. v. 20; 1 Peter iv. 3; Col. iii. 5. In the last of these passages it is used to describe the sin of covetousness or "mammon-worship." In the other places it indicates with the utmost generality all the rites and practices of those special forms of paganism with which Christianity first came into collision. It can only be understood by reference to the LXX., where *εἰδωλον* (like the word "idol" in A.V.) occasionally translates indifferently no fewer than 16 words by which in the Old Testament the objects of what the later Jews called "strange worship" are denoted (see *Encyclopædia Biblica*). In the widest acceptance of the word, idolatry in any form is absolutely forbidden in the second commandment, which runs: "Thou shalt not make unto thee a graven image; [and] to no visible shape in heaven above, or in the earth beneath, or in the water under the earth, shalt thou bow down or render service." (See DECALOGUE.)

It is obvious that two religious votaries in an attitude of reverence before an image may be moved by very different ideas of what the image is and signifies, although their outward attitude is the same. The one may regard it as merely an image, picture, or representation of a higher being, and in itself void of value or power. Its value is that of mere resemblance or some kind of acquired association. But the other may regard it as the tenement or vehicle of the god and fraught with Divine influence. In modern Christendom the former is the attitude which the Roman Church officially inculcates towards sacred pictures and statues; they are intended to convey to the eyes of the faithful, especially to the illiterate among them, facts about Jesus, the Virgin, and the Saints. The other attitude is that into which simple-minded peasants may easily lapse, as it is that which characterizes other religions, ancient or modern, which use images of any kind; and it is this attitude which may be conveniently called "idolatry" or image-worship.

The invectives against idolatry of the early Jewish and Christian apologists, of Philo, Minucius, Felix, Tertullian, Arnobius, Lactantius, and others, throw light on the question how an ancient pagan regarded his idols. One capital argument of the Christians was the absurdity of a man making an idol and then adoring or being afraid of the work of his own hands. Lactantius preserves

the answer of the pagans so criticized (*De origine erroris*, ii. 2): we do not, they said, fear the images themselves, but those beings after whose likeness they were fashioned and by whose names they were consecrated. And Augustine (*De civ. dei*, viii. 23) relates how, according to Hermes, the spirits entered "by invitation" so that the images became "bodies of the gods." Image-worship is essentially a form or rather an outcome of animism, now known to represent a type of religion arising subsequently to its really primitive forms. An image fashioned like a god and having this advantage over a mere stock or stone, that it declares itself and reveals at a glance to what god it is sacred, is believed to attract and influence the god to choose it as his home and tenement. Religious ceremonial is much more hopeful and efficacious for a worshipper who thus has means of approaching the god he worships in visible and tangible form, and even of coercing it. Having the god thus at hand and bound up with the material object, the simple-minded worshipper can punish it if his prayers are left unanswered (*cf.* Tylor, *Primitive Culture*, ii. 170). Suetonius relates (Aug. 16) that Augustus, having lost some ships in a storm, punished Neptune by refusing to allow his image to be carried in procession at the games. See RELIGION (*History of*), and ANIMISM with references there to be found.

BIBLIOGRAPHY.—On the whole subject see art. "Images and Idols" in Hastings, *Encyclopædia of Religion and Ethics*, vol. vii. (1914), with extensive bibliography and references; also Tylor, *Primitive Culture* (ed. 1903); Farnell, *Evolution of Religion* (1905).

IDOMENEUS (ē-dōm-ēn-ūs), in Greek legend, son of Deucalion, grandson of Minos and Pasiphaë, and king of Crete. He courted Helen, and took a distinguished part in the Trojan War. According to Homer (*Odyssey*, iii. 191), he returned home safely with all his countrymen who had survived the war; in later tradition, having been overtaken by a violent storm, he vowed to sacrifice to Poseidon the first living thing that met him when he reached home. This proved to be his son, whom he slew in accordance with his vow; whereupon a plague broke out and Idomeneus was driven out. He fled to the district of Sallentum in Calabria, and subsequently to Colophon in Asia Minor, where he settled near the temple of the Clarian Apollo and was buried on Mt. Cercaphus (Virgil, *Aeneid*, iii. 121, 400, 531, and Servius on those passages). But the Cretans showed his grave at Cnossus, where he was worshipped as a hero with Meriones (Diod. Sic. v. 79).

For this story (a well-known *märchen*, "Home-comer's Vow," *cf.* Jephtha's daughter) see H. J. Rose *Handbook of Greek Mythology* (1928), ch. x.

IDRIA, a mining town in the province of Gorizia, Italy, 29 m. N.E. by road from Gorizia. Pop. (1921) 5,041 (town), 5,592 (commune). It is in the narrow Alpine valley of the Idria, an affluent of the Isonzo, and has rich mines of quicksilver accidentally discovered in 1490. The mercurial ore lies in a bed of clay slate, and is found both mingled with schist and in the form of cinnabar. The yield of pure metal is high compared with the amount of the refuse. The mines of Idria rank second to those of Almaden in Spain, which are the richest in the world.

IDRIALIN, a mineral wax accompanying the mercury ore in Idria. According to Goldschmidt it can be extracted by means of xylol, amyl alcohol or turpentine; also without decomposition, by distillation in a current of hydrogen, or carbon dioxide. It is a white crystalline body, with difficulty fusible, boiling above 440° C. (824° F.), of the composition C₁₀H₂₈O. Its solution in glacial acetic acid, by oxidation with chromic acid, yields a red powdery solid and a fatty acid fusing at 62° C., and exhibiting all the characters of a mixture of palmitic and stearic acids.

IDRISI or Edrisi (Abu Abdallah Mohammed Ibn Mohammed Ibn Abdallah Ibn Idrisi, *c.* A.D. 1099–1154), Arabic geographer. His great-grandfather, Idrisi II., "Biamrillah," a member of the princely house which had reigned as caliphs in north-west Africa, was prince of Malaga. After his death in 1055, Malaga was seized by Granada, and the Idrisi family then probably migrated to Ceuta, where a freedman of theirs held power. Here the geographer was born in A.H. 493 (A.D. 1099). He studied at Cordova and visited before A.D. 1154, both Lisbon and

the mines of Andalusia. He had also resided near Morocco city, and once was at (Algerian) Constantine. In A.D. 1117 he visited the cave of the Seven Sleepers at Ephesus; he probably travelled extensively in Asia Minor. Some have inferred that he had seen part of the coasts of France and England. Roger II. of Sicily (1101-54) invited him to his court between 1125 and 1150. Idrisi made for the Norman king a celestial sphere and a disk representing the known world of his day—both in silver. Roger bestowed on him rich presents, and employed him in the compilation of a fresh description of the "inhabited earth" from observation. The king and his geographer sent emissaries to various countries to observe, record and design; and Idrisi inserted in the new geography the information they brought. Thus was gradually completed (by the month of Shawwal, A.H. 548=mid-January, A.D. 1154), the famous work, best known, from its patron and originator, as *Al Rojari*, but whose fullest title seems to have been, *The going out of a Curious Man to explore the Regions of the Globe, its Provinces, Islands, Cities and their Dimensions and Situation*. This has been abbreviated to *The Amusement of him who desires to traverse the Earth*, or *The Relaxation of a Curious Mind*. The title of *Nubian Geography*, based upon Sionita and Hezronita's misreading of a passage relating to Nubia and the Nile, is misleading. The *Rogerian Treatise* contains a full description of the world as far as it was known to the author. The "inhabited earth" is divided into seven "climates," beginning at the equinoctial line, and extending northwards to the limit at which the earth was supposed to be rendered uninhabitable by cold. Each climate is then divided by perpendicular lines into eleven equal parts, beginning with the western coast of Africa and ending with the eastern coast of Asia. The whole world is thus formed into 77 equal square compartments. The inconveniences of the arrangement (ignoring all divisions, physical, political, linguistic or religious, which did not coincide with those of his "climates") are obvious.

We find few traces of his influence on European thought and knowledge. The chief exception is perhaps in the delineation of Africa in the world-maps of Marino Sanuto (q.v.) and Pietro Vesconte. His account of the voyage of the *Maghrurin* or "Deceived Men" of Lisbon in the Atlantic (a voyage on which they seem to have visited Madeira and one of the Canaries) may have had some effect in stimulating the later ocean enterprise of Christian mariners; but we have no direct evidence. In spite of the record of the Lisbon Wanderers, he shares the common Muslim dread of the black, viscous, stormy and wind-swept waters of the western ocean, whose limits no one knew, and over which thick and perpetual darkness brooded. But his breadth of view, his recognition of scientific truths (such as the roundness of the world) and his wide knowledge and intelligent application of preceding work (such as that of Ptolemy, Masudi and Al Jayhani) must not be forgotten. He also preserves and embodies a considerable amount of private and special information—especially as to Scandinavia, portions of the African coast, the river Niger (whose name is perhaps first to be found, after Ptolemy's doubtful Nigeir, in Idrisi), portions of the African coast, Egypt, Syria, Italy, France, the Adriatic shore-lands, Germany and the Atlantic islands. Unfortunately the place-names are often illegible or hopelessly corrupted in the manuscripts. Idrisi's world-map, with all its shortcomings, is perhaps the best product of the Mohammedan cartography of the middle ages.

Besides the *Rojari*, Idrisi wrote another geographical work cited by Abulfida as *The Book of Kingdoms*, but apparently entitled by its author *The Gardens of Humanity and the Amusement of the Soul*. This was composed for William the Bad (1154-66), son and successor of Roger II., but is now lost.

Two manuscripts of Idrisi exist in the Bibliothèque Nationale, Paris, and two others in the Bodleian Library, Oxford. One of the English mss., brought from Egypt by Greaves, is illustrated by a map of the known world, and by 33 sectional maps (for each part of the first three climates). The second manuscript, brought by Pococke from Syria, is dated A.H. 906, or A.D. 1500. It consists of 320 leaves, and is illustrated by one general and 77 particular maps. The general map was published by Dr. Vincent in his *Periplus of the Erythraean Sea*. A copy of Idrisi's work in the Escorial was destroyed by the fire of 1671.

A French translation of the whole of Idrisi's geography, based on one

of the mss. of the Bibliothèque Nationale, Paris, was published by Amédée Jaubert in 1836-40, and forms volumes v. and vi. of the *Recueil de voyages* issued by the Paris Société de Géographie. Part of a contemplated critical edition was prepared by de Goeje—*Description de l'Afrique et de l'Espagne par Edrisi, texte arabe, publié avec une traduction, des notes et un glossaire par R. Dozy et M. J. de Goeje* (Leiden, E. J. Brill, 1866). Other parts of Idrisi's work have been separately edited; e.g., "Spain" (*Descripción de España de . . . Al-Idrisi*), by J. A. Conde, in Arabic and Spanish (Madrid, 1799); "Sicily" (*Descrizione della Sicilia . . . di Elidrisi*), by P. D. Magri and F. Tardia (Palermo, 1764); "Italy" (*Italia d scritta nel "libro del Re Ruggero," compilato da Edrisi*), by M. Amari and C. Schiaparelli, in Arabic and Italian (Rome, 1883); "Syria" (*Syria descripta a . . . El Edrisio . . .*), by E. F. C. Rosenmüller, in Arabic and Latin, 1825, and (*Idrisii . . . Syria*), by J. Gildemeister (Bonn, 1885) (the last a Beilage to vol. viii. of the *Zeitschrift d. deutsch. Palästina-Vereins*). See also M. Casiri, *Bibliotheca Arabico-Hispana Escorialensis* (2 vols., Madrid, 1760-70); V. Lagus, "Idrisii notitiam terrarum Balticarum ex commercii Scandinavorum et Italarum . . . ortam esse" in *Atti del IV° Congresso internaz. degli orientalisti in Firenze*, p. 395 (Florence, 1880); R. A. Brandel, "Om och ur den arabiske geografen Idrisi," *Akad. afhand.* (Upsala, 1894).

IDUMAEA, the Greek equivalent of Edom (עֲדָם), a territory which, in the works of the Biblical writers, is considered to lie S.E. of the Dead Sea, between the land of Moab and the Gulf of Akaba. The apparently theophorous name Obed-Edom (2 Sam. vi. 10) shows that Edom is the name of a divinity.

The early history of Edom is obscure; Egyptian references to it are few, and do not give us much light regarding its early inhabitants. In the early records of the Pentateuch, the country is often referred to by the name of Seir, the general name for the whole range of mountains on the east side of the Jordan-Araba depression south of the Dead Sea. These mountains were occupied, as early as we can find any record, by a cave-dwelling aboriginal race known as Horites, who were smitten by the much-discussed king Chedorlaomer (Gen. xiv. 6) and according to Deut. ii. 22 were driven out by the Semitic tribes of Esau's descendants. The Horites are to us little more than a name, though the discovery of cave-dwellers of very early date at Gezer in the excavations of 1902-1905 has enabled us to form some idea as to their probable culture-status and physical character.

The occupants of Edom during practically the whole period of Biblical history were the Bedouin tribes which claimed descent through Esau from Abraham, and were acknowledged by the Israelites (Deut. xxiii. 7) as kin. That they intermarried with the earlier stock is suggested by the passage in Gen. xxxvi. 2, naming, as one of the wives of Esau, Aholibamah, daughter of Zibeon the Horite (corrected by verse 20). Among the peculiarities of the Edomites was government by certain officials known as אֲדָמִים, which the English versions (by too close a reminiscence of the Vulgate *duces*) translate "dukes." The now naturalized word "sheikhs" would be the exact rendering. In addition to this Bedouin organization there was the curious institution of an elective monarchy, some of whose kings are catalogued in Gen. xxxvi. 31-39 and 1 Chron. i. 43-54. These kings reigned at some date anterior to the time of Saul. No deductions as to their chronology can be based on the silence regarding them in Moses's song, Exodus xv. 15. There was a king in Edom (Num. xx. 14) who refused passage to the Israelites in their wanderings.

In later times by the constant westward pressure of the eastern Arabs, which (after the restraining force of the great Mesopotamian kingdoms was weakened) assumed irresistible strength, the ancient Edomites were forced across the Jordan-Araba depression, and with their name migrated to the south of western Palestine. In 1 Maccabees v. 65 we find them at Hebron, and this is one of the first indications that we discover of the cis-Jordanic Idumaea of Josephus and the Talmud.

Josephus used the name Idumaea as including not only Goba-litis, the original Mount Seir, but also Amalekitis, the land of Amalek, west of this, and Akrabatine, the ancient Acrabbim, S.W. of the Dead Sea. Jerome describes Idumaea as extending from Beit Jibrin to Petra, and ascribes the great caves at the former place to cave-dwellers like the aboriginal Horites. Ptolemy's account presents us with the last stage, in which the name Idumaea is entirely restricted to the cis-Jordanic district, and the old trans-Jordanic region is absorbed in Arabia. (R. A. S. M.; X.)

IDUN or **IDUNA**, in Scandinavian mythology, the goddess of youth and spring, daughter of the dwarf Svald, wife of Bragi, was keeper of the golden apples, the eating of which preserved to the gods their eternal youth. Idun personifies the year between March and September, and her myth represents the annual imprisonment of spring by winter.

IDYL or **IDYLL**, a short poem of a pastoral or rural character, in which something of the element of landscape is preserved or felt. The earliest commentators of antiquity used the term to designate a great variety of brief and homely poems, in which the description of natural objects was introduced, but the pastoral idea came into existence in connection with the Alexandrian school and particularly with Theocritus, Bion and Moschus, in the 3rd century before Christ. It appears, however, that *εἰδύλλιον* was not, even then, used consciously as the name of a form of verse, but as a diminutive of *εἶδος*, and merely signified "a little piece in the style of" whatever adjective might follow. Thus the idyls of the pastoral poets were *εἰδύλλια αἰπολικά*, little pieces in the goatherd style. We possess ten of the so-called "Idyls" of Theocritus, and these are the type from which the popular idea of this kind of poem is taken. The word was revived at the Renaissance. In 1658 the English critic, Edward Phillips, defined an "idyl" as "a kind of eclogue," but it was seldom used to describe a modern poem. The general use, or abuse, of the word in the second half of the 19th century, both in English and French, arises from the popularity of two works, by two eminent poets. The *Idylles héroïques* (1858) of Victor de Laprade and the *Idylls of the King* (1859) of Tennyson enjoyed a success in either country which led to a wide imitation of the title among those who had, perhaps, a very inexact idea of its meaning. On the whole, it is impossible to admit that the idyl has a place among definite literary forms.

IESI (anc. *Aesis*), a town and episcopal see of the Marches, Italy, province of Ancona, 17 m. W. by S. from Ancona town by rail, 318 ft. above sea-level. Pop. (1921) 15,759 (town), 25,949 (commune). It lies on the left bank of the river Aesis (mod. Esino). It still retains its picturesque mediaeval town walls. S. Marco is an interesting 13th century church. The Palazzo del Comune is a fine, simple, early Renaissance building (1487-1503) by Francesco di Giorgio Martini. The courtyard with its loggia was built by Andrea Sansovino in 1519. The picture gallery contains some good pictures by Lorenzo Lotto. The castle was built by Baccio Pontelli (1488). Iesi was the birthplace of the emperor Frederic II. (1194), and also of the composer Giovanni Battista Pergolesi (1710-1736). The silk spinning industry is of considerable importance. The Aesis formed the boundary of Italy proper from about 250 B.C. to the time of Sulla (c. 82 B.C.); and, in Augustus' division of Italy, that between Umbria (the 6th region) and Picenum (the 5th).

See L. Marinelli in *Cronache d'Arte* iv. (1928) "Le Mure di Iesi."

IFFLAND, AUGUST WILHELM (1759-1814), German actor and dramatic author, was born at Hanover on April 19, 1759. At 18 the boy ran away to Gotha in order to prepare himself for a theatrical career. He was taught by Hans Ekhof, and in 1779 was engaged at the Mannheim theatre, then rising into prominence. In 1796 he settled in Berlin, where he became director of the national theatre of Prussia; and in 1811 he was made general director of all representations before royalty. Iffland produced the classical works of Goethe and Schiller with conscientious care; but the kind of play in which he was most at home, both as actor and playwright, was the domestic drama, the sentimental play of everyday life. Among his best-known plays are *Die Jäger*, *Dienstpflcht*, *Die Advokaten*, *Die Mündel* and *Die Hagestolzen*. In 1798-1802 he issued his *Dramatische Werke* in 16 volumes, to which he added an autobiography (*Meine theatralische Laufbahn*). In 1807-09 Iffland brought out two volumes of *Neue dramatische Werke*. Iffland died at Berlin on Sept. 22, 1814.

See K. Duncker, *Iffland in seinen Schriften als Künstler, Lehrer, und Direktor der Berliner Bühne* (1859); W. Koffka, *Iffland und Dalberg* (1865); and Lampe, *Studien über Iffland als Dramatiker* (Celle, 1899). Iffland's interesting autobiography, *Meine theatralische Laufbahn*, was republished by H. Holstein in 1885.

IGARA, a people closely resembling the Yoruba, inhabiting the provinces of Munshi and Nassarawa, Northern Nigeria, and who speak a Yoruba dialect.

See Meek, *The Northern Tribes of Nigeria* (1925).

IGLAU: see JIHLAVA.

IGLESIAS, a town and episcopal see of Sardinia in the province of Cagliari, 34 m. W.N.W. from Cagliari by rail, 620 ft. above sea-level. Pop. (1921) 11,651 (town), 19,844 (commune). It is a mining centre with a school of mines in the southwestern mountains. Minerals go by a small railway via Monteponi (with its large lead and zinc mine) to Portovesme (15 m. S.W. of Iglesias in the sheltered gulf of Carloforte) where they are shipped. The cathedral of Iglesias, built by the Pisans, has a good façade (restored); the interior is late Spanish Gothic. San Francesco is a fine Gothic church with a gallery over the entrance, while Sta. Chiara and the church of the Capuchins (the former dating from 1285) are transitional Romanesque Gothic. The battlemented town walls are well preserved; the castle, built in 1325, now contains a glass factory.

IGLESIAS POSSE, PABLO (1850-1925), Spanish politician was born at El Ferrol on Oct. 15, 1850. On the death of his father he was placed in a foundling asylum where after repeated attempts at escape he remained for some years. In 1871 he became secretary of the International Proletarian Federation and in 1872 founded the Typographical Societies of which he became president in 1885. He helped form the first Spanish Socialist group in 1879 and was elected to the House of Deputies in 1910. In 1923, when Primo de Rivera overthrew the constitution and closed the doors of the Cortes, he was chief of the Parliamentary Socialist Party. He became editor of *El Socialista*, the organ of the Spanish labour movement in 1886. For activities on behalf of the workers he served eight terms of imprisonment. He died in Madrid on Dec. 8, 1925.

See Meliá, *Pablo Iglesias Posse. Rasgos de su vida íntima* (1926).

IGNATIEV, NICHOLAS PAVLOVICH, COUNT (1832-1908), Russian diplomatist, was born at St. Petersburg (Leningrad) on Jan. 29, 1832. At 17 he became an officer of the Guards. His diplomatic career began at the Congress of Paris, after the Crimean War, where he took an active part as military attaché in the negotiations regarding the rectification of the Russian frontier on the Lower Danube. Two years later (1858) he was sent with a small escort on a dangerous mission to Khiva and Bokhara. The khan of Khiva laid a plan for detaining him as a hostage, but he returned safely, after concluding with the khan of Bokhara a treaty of friendship. He was Russian envoy at Peking when the Chinese Government was terrified by the advance of the Anglo-French expedition of 1860 and the burning of the Summer Palace; he used the occasion to secure for Russia not only the left bank of the Amur, the original object of the mission, but also a large extent of territory and sea-coast south of that river. Ignatiev was ambassador at Constantinople from 1864 till 1877. Here his chief aim was to liberate from Turkish domination and bring under the influence of Russia the Christian nationalities in general and the Bulgarians in particular. His diplomacy led up to the Russo-Turkish war of 1877-78, at the close of which he negotiated with the Turkish plenipotentiaries the treaty of San Stefano. Ignatiev then retired in semi-disgrace. After the accession of Alexander III. in 1881, he was appointed minister of the interior to carry out a nationalist, reactionary policy, but was dismissed in 1882. He died on July 3, 1908.

IGNATIUS (Ἰγνάτιος), bishop of Antioch, a father of the Church. Our only trustworthy information is derived from the letters which he wrote to various churches on his last journey from Antioch to Rome, and from the short epistle of Polycarp to the Philippians. For the complicated controversy over the three recensions of the letters of Ignatius the reader is referred to the authorities quoted in the bibliography. The general consensus of opinion appears to be that the letters contained in the Medicean ms. at Florence, addressed to the Ephesians, Magnesians, Trallians, Romans, Philadelphians, Smyrnaeans and to Polycarp are genuine, and that they were written in the reign of Trajan. Harnack placed them in the latter years of Trajan or

possibly 117-125. Most scholars date them a few years earlier (110-117).

The letters of Ignatius unfortunately, unlike the Epistles of St. Paul, contain scant autobiographical material. We are told absolutely nothing about the history of his career. The fact that like St. Paul he describes himself as an *ἐκτρώμα* (*Rom.* 9), and that he speaks of himself as "the last of the Antiochene Christians" (*Trall.* 13; *Smyrn.* xi.), seems to suggest that he had been converted from paganism somewhat late in life and that the process of conversion had been abrupt and violent. He bore the surname of Theophorus, *i.e.*, "God-clad" or "bearing God." At the time when the Epistles were written he had just been sentenced to death, and was being sent in charge of a band of soldiers to Rome to fight the beasts in the amphitheatre. The fact that he was condemned to the amphitheatre proves that he could not have been a Roman citizen. We lose sight of him at Troas, but the presumption is that he was martyred at Rome.

But if the Epistles tell us little of the life of Ignatius, they give us an excellent picture of the man himself, and are a mirror in which we see reflected certain ideals of the life and thought of the day. Ignatius, as Schaff says, "is the incarnation of three closely connected ideas: the glory of martyrdom, the omnipotence of episcopacy, and the hatred of heresy and schism."

Zeal for martyrdom in later days became a disease in the Church, but in the case of Ignatius it is the mark of a hero. The heroic note runs through all the Epistles; thus he says:

I bid all men know that of my own free will I die for God, unless ye should hinder me . . . Let me be given to the wild beasts, for through them I can attain unto God. I am God's wheat, and I am ground by the wild beasts that I may be found the pure bread of Christ. Entice the wild beasts that they may become my sepulchre . . . ; come fire and cross and grapplings with wild beasts, wrenching of bones, hacking of limbs, crushings of my whole body; only be it mine to attain unto Jesus Christ (*Rom.* 4-5).

Ignatius constantly contends for the recognition of the authority of the ministers of the church. "Do nothing," he writes to the Magnesians, "without the bishop and the presbyters." The "three orders" are essential to the church; without them no church is worthy of the name (*cf. Trall.* 3). "It is not lawful apart from the bishop either to baptize or to hold a love-feast" (*Smyrn.* 8). Respect is due to the bishop as to God, to the presbyters as the council of God and the college of apostles, to the deacons as to Jesus Christ (*Trall.* 3). These terms must not, of course, be taken in their developed modern sense. The "bishop" of Ignatius seems to represent the modern pastor of a church. As Zahn has shown, Ignatius is not striving to introduce a special form of ministry, nor is he endeavouring to substitute one form for another. His particular interest is not so much in the form of ministry as in the unity of the church. Centrifugal forces were at work.

Ignatius was resisting this fatal tendency which threatened ruin to the faith. The only remedy for it in those days was to exalt the authority of the ministry and make it the centre of church life. It should be noted that (1) there is no trace of the later doctrine of apostolical succession; (2) the ministry is never sacerdotal in the letters of Ignatius. As Lightfoot puts it: "The ecclesiastical order was enforced by him (Ignatius) almost solely as a security for doctrinal purity. The threefold ministry was the husk, the shell, which protected the precious kernel of the truth" (*i. 40*).

Ignatius fights most vehemently against the current forms of heresy. The chief danger to the church came from the Docetists who denied the reality of the humanity of Christ and ascribed to him a phantom body. Hence we find Ignatius laying the utmost stress on the fact that Christ "was *truly* born and ate and drank, was *truly* persecuted under Pontius Pilate . . . was *truly* raised from the dead" (*Trall.* 9). "I know that He was in the flesh even after the resurrection, and when He came to Peter and his company, He said to them, 'Lay hold and handle me, and see that I am not an incorporeal spirit'" (*Smyrn.* 3). Equally emphatic is Ignatius's protest against a return to Judaism. "It is monstrous to talk of Jesus Christ and to practise Judaism, for Christianity did not believe in Judaism but Judaism in Christianity" (*Magn.* 10).

As far as Christology is concerned, there are two points to be noted: (1) Ignatius is the earliest writer outside the New Testament to describe Christ under the categories of current philosophy; *cf.* the famous passage in *Eph.* 7. "There is one only physician, of flesh and of spirit (*σαρκικός αἰὲν πνευματικός*), generate and ingenerate (*γεννητὸς καὶ ἀγεννητος*), God in man, true life in death, son of Mary and son of God, first passible and then impassible" (*πρῶτον παθητὸς καὶ ἀπαθής*). (2) Ignatius is also the first writer outside the New Testament to mention the Virgin Birth, upon which he lays the utmost stress. "Hidden from the prince of this world were the virginity of Mary and her child-bearing and likewise also the death of the Lord, three mysteries to be cried aloud, the which were wrought in the silence of God" (*Eph.* 19). Here, it will be observed, we have the nucleus of the later doctrine of the deception of Satan. In regard to the Eucharist also later ideas occur in Ignatius. It is termed a *μυστήριον* (*Trall.* 2), and the influence of the Greek mysteries is seen in such language as that used in *Eph.* 20, where Ignatius describes the Eucharistic bread as "the medicine of immortality and the antidote against death."

When Ignatius says, too, that "the heretics abstain from Eucharist because they do not allow that the Eucharist is the flesh of Christ," the words seem to imply that materialistic ideas were beginning to find an entrance into the church (*Smyrn.* 6). Other points that call for special notice are: (1) Ignatius's rather extravagant angelology. In one place, for instance, he speaks of himself as being able to comprehend heavenly things and "the arrays of angels and the musterings of principalities" (*Trall.* 5). (2) His view of the Old Testament. In one important passage Ignatius emphatically states his belief in the supremacy of Christ even over "the archives" of the faith, *i.e.*, the Old Testament: "As for me, my archives—my inviolable archives—are Jesus Christ, His cross, His death, His resurrection and faith through Him" (*Philadel.* 8).

See T. Zahn, *Ignatius von Antiochien* (Gotha, 1873); J. B. Lightfoot, *Apostolic Fathers*, part ii. (London, 2nd ed., 1880); F. X. Funk, *Die Echtheit der ignat. Briefe* (Tübingen, 1892); A. Harnack, *Chronologie der altchristlichen Litteratur* (Leipzig, 1897). There is a good bibliography in G. Krüger, *Early Christian Literature* (Eng. trans., 1897, pp. 28-29); Rackl, *Die Christologie des heil. Ignaz von Antiochien* (1914). See also APOSTOLIC FATHERS.

IGNIS FATUUS, the name applied to the pale flame, also called will-o'-the-wisp and jack-o'-lantern, sometimes seen flickering over marshy ground and, it is said, over churchyards. No entirely satisfactory explanation has been put forward but it is generally believed that the effect is due to the spontaneous ignition of gases (especially methane or marsh gas, CH₄) produced by the disintegration of dead plant and, possibly, animal matter.

IGNORAMUS, properly an English law term for the endorsement on the bill of indictment made by a grand jury when they "throw out" the bill, *i.e.*, when they do not consider that the case should go to a petty jury. The expression is now obsolete, "not a true bill," "no bill," being used. The expressions "ignoramus jury," "ignoramus Whig," etc., were common in the political satires and pamphlets of the years following on the throwing out of the bill for high treason against the 2nd earl of Shaftesbury in 1681. The application of the term to an ignorant person dates from the early part of the 17th century. This term, in a legal sense, is not in use in the United States.

IGNORANCE. In the law among the English-speaking peoples, as in Roman law, ignorance of the law is, in general, no ground for avoiding the consequences of an act. As regards criminal offences, the maxim as to *ignorantia juris* admits of no exception, even in the case of a foreigner temporarily in England, who is likely to be ignorant of English law. In Roman law the harshness of the rule was mitigated in the case of women, soldiers and persons under the age of 25, unless they had good legal advice within reach (*Dig.* xxii. 6. 9), while in England judges often inflict mitigated sentences when a criminal did not and could not reasonably be expected to know the law, especially if it be very recent. Ignorance of foreign law is ignorance of fact. A compromise of claims, doubtful in law, is good and cannot be

upset by subsequent solving of the doubt (*Stewart v. Stewart* 6 Cl. and F. 911). Ignorance of a matter of fact may in general be alleged in avoidance of the consequences of acts and agreements, but such ignorance cannot be pleaded where it is the duty of a person to know, or where, having the means of knowledge at his disposal, he wilfully or negligently fails to avail himself of it. (See CONTRACT.)

In logic, ignorance is that state of mind which for want of evidence is equally unable to affirm or deny one thing or another. Doubt, on the other hand, can neither affirm nor deny because the evidence seems equally strong for both. (For *Ignoratio Elenchi* [irrelevant conclusion] see FALLACY.)

IGNORANTINES, a name sometimes given to the Brothers of the Christian Schools, owing to a clause in the constitution of the order forbidding the admission of priests with a theological training. (See INSTITUTE OF THE CHRISTIAN BROTHERS.)

IGOROT, a tribe of Luzon, in the Philippines, calling itself *Ifugao*: a name used separately also for a subtribe of Igorot and

BY COURTESY OF THE SMITHSONIAN INSTITUTION

IGOROT FAMILY ENGAGED IN DOMESTIC PURSUITS OUTSIDE THEIR HOME

the linguistic equivalent of *apayao*, a name used for a member of the other group of Luzon tribes, which includes the Ilocano, Tinguian and Kalinga groups. (See TINGUIAN.) Their political unit is a village State, divided into wards with separate buildings for the unmarried of either sex, regulated by the old men, and having a graded nobility of wealth. Irrigated rice is cultivated, buffalos, pigs, fowls and dogs are kept, the latter being eaten. Marriage is forbidden to first cousins and monogamy prevails. Tattooing is practised, the sun being tattooed on the back of the hand (*cf.* KAREN). The spear and axe are the weapons used; gold, copper and iron are mined, smelted and worked, the piston-bellows being employed, and metal cast by the *cire perdue* process. The dead are dried in a sitting posture and are placed on their backs in graves or caves, wooden figures being made to accommodate the soul. Near each village is a spirit tree. Souls dying natural deaths are also believed to go to a home of the dead under ground, while those dying in battle or child-birth ascend to heaven (*cf.* DAFLA), the abode of Lumawig, who is worshipped as a Creator and culture hero. Rich men are buried in terraces. Head-hunting (*q.v.*) is practised (*cf.* NAGA, and ASIA: *Ethnology*).

See Jenks, *Bontoc Igorot* (1905).

IGUALADA, a town of north-eastern Spain, in the province of Barcelona, on the left bank of the river Noya, a right-hand tributary of the Llobregat, and at the northern terminus of the Igualada-Martorell-Barcelona railway. Pop. (1920) 12,512. Igualada is the central market of a rich agricultural and wine-producing district. The local industries, chiefly developed since 1880, include the manufacture of cotton, linen, wool, ribbons, cloth, chocolate, soap, brandies, leather, cards and nails. The famous mountain and convent of Montserrat or Monserrat (*q.v.*) is 12 m. east.

IGUANA, the name strictly applicable to the lizards of the family Iguanidae; the same name, or its corruption "goanna,"

is sometimes misapplied to the monitors (family Varanidae). With three exceptions all the genera (numbering about 50 and containing over 400 species) belong to the New World; the exceptional genera are *Brachylophus* in the Fiji islands and *Hoplurus* and *Chalarodon* in Madagascar. The family can be regarded as the New World analogue of the Old World Agamidae, which family it closely resembles in its structure and in the modifications which its members have undergone. The only absolute distinction between the two families is in the position of the teeth; in the Agamidae they are fused to the crest of the jaw bones and in the Iguanidae attached to the inner slope below this crest. In many, however, the teeth are peculiar in being blade- or spear-shaped, with the upper cutting edges strongly serrated. As a rule the iguanas are clothed with small scales and have a large dewlap, a pouch situated beneath the head and neck, and often a crest from the nape of the neck to the extremity of the tail; this crest is composed of narrow, elongate scales which gradually diminish in size posteriorly. The tongue is short and not protractile.

Perhaps the best known species is the common iguana (*Iguana tuberculata*) which occurs throughout tropical Central and South America. Reaching a length of as much as 6 ft., this animal is much sought for as an article of diet, the flesh being greatly esteemed; in habits it is arboreal, its favourite haunts being trees which overhang water, into which it will unhesitatingly plunge if disturbed. Like most of the arboreal species, the ground colour is greenish, relieved in this particular case by brown bands which, though indistinct on the body, form regular annuli on the tail. The food consists largely of tender leaves and fruits but the lizards are by no means averse to a mixed diet and will readily eat small birds and mammals. Another semi-arboreal genus is the likewise tropical American *Basiliscus*, whose members exhibit some curious modifications. The body is compressed from side to side, the tail very long and whip-like, the hinder part of the head produced into a flat lobe like a cock's comb and the outer edges of the toes provided with a wide fringe of elongate scales; the males of all species have a crest along the back but in two species (*B. basiliscus* and *B. plumifrons*) this is enormously developed, being as deep as the body, supported by rays like the fins of a fish, and covered with very thin scales. In addition to these structural peculiarities they have the power, shared only by a few other forms of this family, of being able

COMMON IGUANA (IGUANA TUBERCLATA) OF TROPICAL AMERICA

to run across the surface of water; if disturbed near the water they scutter across it on their hind-limbs, the body being held almost upright with the tail raised as a counterpoise and the fore-limbs folded against their sides. *Basiliscus* itself does not dive, but the related *Derioptyx* of Cuba rushes across the surface in the same way and in some quiet corner dives to the bottom, where it remains until the alarm has passed. *Amblyrhynchus* has achieved fame as the only marine lizard. Its aquatic nature has usually been exaggerated, however, and actually it seldom takes to the water. Large herds of these lizards used to

frequent the rocky shores of the Galapagos islands feeding on the sea-weeds between tide-marks.

The terrestrial species of the family are usually duller in colour than the arboreal ones and the body is, as a rule, depressed rather than compressed; this depression has been carried to an extreme in the so-called horned toads (*Phrynosoma*) of the deserts of the United States and Mexico. As well as being depressed, they have, like many desert dwelling animals, developed an armour of spines the largest of which occur on the back of the head and neck and are relatively huge. This lizard offers a very close analogy to the Australian moloch lizard, an agamid which under similar conditions has developed a very similar appearance. An unique characteristic of the members of this genus is their ability to squirt a fine jet of blood from the eye; this extraordinary phenomenon, which has never been satisfactorily explained, only occurs under stress of great emotion, fright or anger. The lizard puffs itself up until the eyes bulge and then a very fine stream of blood is shot out of the eye, sometimes to a distance of five feet. No special mechanism for this discharge has been found and the eye does not appear to be injured.

Another peculiarly modified genus is *Anolis* which occurs throughout the warmer districts of both North and South America and which is particularly abundant among the West Indian islands. Many of the lizards of this genus have the basal joints of their fingers and toes dilated and covered with transverse lamellae like those of a gecko and these adhesive pads, together with the powerful claws, render the animals excellent climbers. They have wonderful powers of changing colour, rivalling in this respect the chamaeleons; in fact they are frequently called "American chamaeleons." The males often have enormously developed dewlaps which may be brilliantly coloured and can be expanded and contracted at will, like a fan.

Most iguanids reproduce by means of eggs though a few species are ovoviviparous. (H. W. P.)

IGUANODON, a large extinct amphibious reptile. Its remains were first discovered in the Wealden (Lower Cretaceous) estuarine deposits of Sussex by G. A. Mantell, who named it *Iguanodon*, in allusion to the resemblance between its teeth and those of the lizard *Iguana* of tropical America. In 1877 several nearly complete skeletons now in the Royal Museum of Natural History at Brussels, were found in the Wealden rocks near Mons, Belgium. More recently another nearly complete skeleton, now in the British Museum, was found by R. W. Hooley in the same

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
SKELETON (RECONSTRUCTED) OF THE IGUANODON, AN EXTINCT MAMMOTH REPTILE THAT RANGED SOUTHERN ENGLAND AND NORTHERN EUROPE DURING THE CRETACEOUS PERIOD

rocks at Atherfield in the Isle of Wight. *Iguanodon* is interesting as being the first gigantic extinct reptile which it was attempted to restore by comparison with a modern lizard. Mantell's early restoration proved a failure, because it was unknown at the time that this reptile belonged to an extinct order, Dinosauria (*q.v.*), which differed from all modern reptiles in having limbs adapted for supporting the body when at rest, and in having more than two vertebrae fused together to form a sacrum above the hindlimbs like the sacrum of birds and mammals. Like nearly all the more active dinosaurs, it had comparatively large and heavy hind

quarters, passing into a long tail; and footprints show that it walked only on its hind limbs, using the tail for balancing the fore-quarters.

The typical species, *I. mantelli*, is from 5 to 6 metres long, and must have measured about 4 metres in height when standing upright. The largest known species seem to have been sometimes 10 metres long. The head is relatively large, laterally compressed, and about twice as long as deep. Its long axis is bent downwards for cropping its vegetable food. The front of both jaws is toothless and must have been covered with a horny beak. The lower half of the beak is supported by a separate "prementary" bone. The edge of each jaw further back bears a single row of teeth, which differ from those of all existing reptiles in being often worn down to stumps by mastication. Under the teeth actually in use are numerous successional teeth. The neck and front half of the back are made flexible by ball-and-socket joints between the vertebrae. The front half of the tail is deep and laterally compressed, evidently for swimming. The small fore-limbs must have been very mobile, and the thumb in the five-fingered hand is reduced to a bony spur. The supporting bones of the hind-limbs are much like those of ostriches, though they differ in never being fused into one mass. The three toes of the heavy hind-foot are so much like those of birds that the fossilized footprints were originally mistaken for those of birds. The body lacks armour, but the skin was hardened with a close covering of small irregular tubercles. Footprints are common on the Wealden sandstones of Sussex, and several series have been observed without any trace of the forefeet and rarely a mark of the tail.

Nothing is satisfactorily known about the possible ancestors of *Iguanodon*, and few of its closely allied contemporaries have been discovered. The comparatively small *Hypsilophodon*, which occurs with it in the Wealden of the Isle of Wight, differs in having the teeth extending to the front of each jaw. The equally small *Psittacosaurus*, from rocks of nearly the same geological age in Mongolia, has the toothless front of the jaws shaped almost like the beak of a parrot. The successors of *Iguanodon*, the Trachodontidae, in the Upper Cretaceous, were more adapted for aquatic life, and their toothless beak was shaped almost like the end of the bill of a duck. The side of each jaw bore a powerful grinding dentition, several rows of teeth being in use at one time. Many of the trachodonts were peculiar in exhibiting a bony crest on the top of the head.

See L. Dollo, *Bull. Mus. Roy. d'Hist. Nat. Bruxelles* (1882-84); R. W. Hooley, *Quart. Journ. Geol. Soc.* (1925); also a special *Guide* published by the Royal Museum of Natural History, Brussels.

(A. S. W.)

IGUVIUM (mod. Gubbio, *q.v.*), a town of Umbria, among the mountains, about 23 m. north-north-east of Perugia and connected with it by a by-road, which joined the Via Flaminia near the temple of Iuppiter Appenninus, at the modern Scheggia. It appears to have been important in pre-Roman times, both from its coins and from the celebrated *tabulae Iguvinae* (see below).

We find it in possession of a treaty with Rome, similar to that of the Camertes Umbri; and in 167 B.C. it was used as a place of safe custody for the Illyrian King Gentius and his sons. After the Social War, in which it took no part, it received full citizen rights and was included in the tribus Clustumina. Under the empire we hear almost nothing of it. Silius Italicus mentions it as subject to fogs. A bishop of Iguvium is mentioned as early as A.D. 413. It was taken and destroyed by the Goths in 552, but rebuilt with the help of Narses. The Umbrian town had three gates only, and probably lay on the steep mountain side as the present town does, while the Roman city lay in the lower ground. Here is the theatre, restored by Cn. Satrius Rufus in the time of Augustus. The diameter of the orchestra is 76½ ft. and of the whole 230 ft.; the stage is well preserved and so are parts of the external arcades of the auditorium. Not far off are ruins probably of ancient baths, and the concrete core of a large tomb with a vaulted chamber within.

Iguvine Tables.—The famous *Iguvine* (less correctly *Eugubine*) *Tables*, were discovered at Iguvium in 1444, bought by

the municipality in 1456, and are still preserved in the town hall. They were originally nine in number, and two of the nine were taken to Venice in 1540 and never reappeared. The existing seven were first published in 1724.

BIBLIOGRAPHY.—Otfried Müller (*Die Etrusker*, 1828), pointed out that though their alphabet was akin to the Etruscan their language was Italic. Lepsius, in his essay *De tabulis Eugubinis* (1833), finally determined the value of the Umbrian signs and the received order of the Tables, pointing out that those in Latin alphabet were the latest. He published what may be called the *editio princeps* in 1841. The first edition, with a full commentary based on scientific principles, was that of Aufrecht and Kirchoff in 1849–51, and on this all subsequent interpretations are based (Bréal, Paris, 1875; Bücheler, *Umbria*, Bonn, 1883, a reprint and enlargement of articles in *Fleckeisen's Jahrbuch*, 1875, pp. 127 and 313). The text is everywhere perfectly legible, and is excellently represented in photographs by the marquis Ranghiasi-Brancalone, published with Bréal's edition. See also R. S. Conway, *Italic Dialects*, 1897.

IHNE, WILHELM (1821–1902), German historian, was born on Feb. 2, 1821, at Fürst and was educated at Bonn. In 1843 he came to England as a private tutor, and after two years of teaching at Elberfeld (1847–49), became headmaster of a school at Liverpool. In 1863 he returned to his native country, and ten years later, was appointed professor at Heidelberg, where he died on May 22, 1902. Ihne's chief publications are: *Forschungen auf dem Gebiet der röm. Verfassungsgeschichte* (1847, Eng. trans. 1853); *Plea for the Emperor Tiberius* (1856), and *Röm. Geschichte* (8 Bde., 1868–90).

IJAW, a people inhabiting the provinces of Owerri and Warri, Southern Nigeria. No tribal organization exists; hereditary chiefs in the towns have civil and religious functions, aided by councils of elders. Extended family groups live side by side. Marriage is permitted between near relations. When the bride-price is high, the wife cannot leave her husband, and children belong to the father; when it is small, divorce is possible and children belong to the mother. The brother inherits. They practise agriculture and arboriculture, are animists, have secret societies and age classes. There are slight indications of totemism.

See P. Amaury Talbot, *The Peoples of Southern Nigeria* (1926).

IJOLITE, in petrology an igneous rock composed essentially of nepheline and an alkaline pyroxene, usually aegirine-augite. The rock was originally described from Russia where it occurs in various parts of the Kola Peninsula. Typically the pyroxene is well crystallized, the nepheline allotriomorphic. Accessory minerals include melanite-garnet, titanite, apatite, cancrinite and calcite. This rock is the plutonic equivalent of the volcanic nephelinites and hypabyssal nepheline dolerites. Ijolites are also known from Norway (Fen district) and British Columbia (Ice river), but they are quite rare. The rocks known as urtite and melteigite are essentially similar assemblages. In the former nepheline largely preponderates, while melteigite is a melanocratic variant with excess pyroxene. (C. E. T.)

IKHNATON (sometimes spelt AKHENATON), the name assumed by Amenhotep IV. of Egypt.

An adequate understanding of the origins and the history of the religious revolution carried through by this earliest known idealist is impossible without some knowledge of the historical and political situation of his generation. When he came to the throne (c. 1375 B.C.) there were plenty of men still living whose fathers had fought in the great wars of Thutmose III., who consolidated the conquests of his ancestors and united the contiguous regions of Asia and Africa into the first stable empire in history. His genius and his far reaching victories made him the first character of universal aspects, the first world hero. Such a towering personality inevitably affected the thought of the early world. The earliest gods of Egypt had been nature-gods. As the great Pharaonic State arose, the impressive figure of the sovereign profoundly influenced religion; the forms of the State passed over into human conceptions of the gods, and the Sun-god, the greatest of them all, was conceived as a pharaoh ruling the other divinities.

When therefore the power of the Pharaohs was extended to include a world empire, this greatly expanded arena of action deeply affected Egyptian conceptions of the Sun-god's realm. In

the career of Thutmose III. the idea of universal power, of a world-empire was personalized and visibly bodied forth. This first great *human* personality of world wide aspects began to affect Egyptian ideas of *divine* personality. Men began to feel the thrill of universalism, expressed, it should be observed, in terms of *political* power. Other relations with the outside world beyond the limits of the Nile valley had not clearly disengaged for the Nile-dwellers the "world idea" as we may call it. For example, a net-work of commercial connections with surrounding countries had arisen centuries earlier and had resulted in a literature of adventure in far-off countries, as illustrated by such tales as the shipwrecked sailor or the story of the wandering hero, Sinuhe; but such knowledge of distant lands had done little toward bringing the great world without into the purview of Egyptian thinking. Neither did the universal power of natural laws, everywhere visibly active in uniform operation, suggest to these early men the world idea. Many a merchant had seen a stone fall in distant Babylon precisely as it did in Egyptian Thebes, but it had not occurred to him or to any man in that far-off age, that the same natural force reigned in these widely separated countries. It was universalism expressed in terms of *imperial power* which first caught the imagination of the thinking men of the Egyptian empire, and disclosed to them the universal sweep of the Sun-god's dominion as a physical fact. In the ancient East monotheism was but imperialism in religion.

The Sun-god Aton.—As early as 1400 B.C. under the magnificent emperor, Amenhotep III., great-grandson of Thutmose III., the expanded conception of the Sun-god's power was gaining currency. In order to give this magnified Sun-god a new identity, not embarrassed by older and more limited conceptions, "Aton," an ancient name for the physical sun, was employed to designate him. When Amenhotep III. died (c. 1375 B.C.), his son and successor, Amenhotep IV., was closely associated with the new ideas. He assumed the office of the High Priest of Aton, with the same title, "Great Seer," as that of the high priest of the old Sun-god Re at Heliopolis. It is clear therefore, that the new movement was closely connected with the old Solar theology and probably with its organized priesthood likewise.

The new and transformed Sun-god was obviously conceived as far more than the merely material sun. It is evident that the young Pharaoh was deifying the light of the sun or its vital heat, which he found accompanying all life. Light or heat plays an important part in the new faith, similar to that which we find it assuming in the early cosmogonic philosophies of the Greeks. In harmony with this conception the god is constantly stated to be everywhere active by means of his "rays." It is perfectly certain that in an age so early in the development of natural science the king could not have had the vaguest notion of the physico-chemical aspects of his assumption that all life issued from the rays of the sun, any more than had the Greeks in dealing with a similar thought. Yet the fundamental idea is surprisingly true, and as we shall see surprisingly fruitful.

With the international arena of his empire in view the Pharaoh devised a new symbol for the new god. It depicted the sun as a disk from which diverging rays radiated downward, each ray terminating in a human hand. As suggesting a power issuing from its celestial source and putting its hand upon the world and the affairs of men, it was a masterly symbol. It broke sharply with tradition, and for that very reason it was capable of practical introduction into the many countries making up the empire; for it could be understood by a foreigner at a glance, and this was far from being the case with any of the traditional symbols of the old Egyptian religion. To indicate the imperial power of Aton, however, Amenhotep IV. did employ an Egyptian device. He now enclosed the god's full name, as already introduced by the king's father, in two royal cartouches identical with those of the Pharaoh, thus suggesting for the god an earthly dominion like that of the Pharaoh.

Conflict Between Amon and Aton.—The king's zeal for the new cult was evident from the beginning. To Thebes, the imperial capital, he gave the new name, "City of the Brightness of Aton," its temple quarter was called, "Brightness of Aton

the Great," while the new Aton sanctuary itself was designated as "Gem-Aton," a term of unknown meaning. The priesthood of Amon who had long been the State god at Thebes, was a rich and influential body, and the high priest of Amon was head of a national sacerdotal organization including all the priesthoods of the country. Politically this Amonite priesthood had gained great power. A bitter conflict thus broke out, at first probably, chiefly between Amon and the intruder Aton, but eventually also between Aton and the older gods. The struggle eventually rendered Thebes intolerable to the young revolutionary. He broke with all the old priesthoods and began a drastic persecution to make Aton the sole god of the empire, not merely in the king's own thought, but in very fact. As far as their visible and external manifestations were concerned, this extermination of the old gods could be and was accomplished. Even the word "gods," the plural of the common noun "god," was carefully expunged from the monuments. In the tomb of Ramose, his father's old prime minister, a tomb still surviving in the Theban cemetery, Amenhotep IV.'s emissaries hewed out the word "gods" no less than nine times, clearly indicating their intentions, notwithstanding three untouched occurrences of the word which escaped their notice and which we still find in out-of-the-way corners of this marvellously sculptured tomb.

The persecution of Amon was especially severe and to-day the splendid monuments of Thebes are still dotted with unsightly holes where the hated god's name once stood. The young iconoclast was even involved in the expungement of his own father's name, Amenhotep, for it contained the name of the hostile god. Living as he probably was, in his father's splendid Theban palace, the wreckage of which is still visible, he finally brought himself to disfigure its sumptuous wall and ceiling decorations with unsightly blemishes where he blotted out his own father's name. With regard to his own name he was himself in the same embarrassing predicament, bearing as he also did, the illustrious throne name "Amenhotep," meaning "He in whom Amon is content." The king therefore cast off his old name, with all its traditional associations of power and splendor, and chose another of similar significance, "Ikhnaton," which means "Aton is satisfied," or "He in whom Aton is satisfied."

The New Capital, Akhetaton.—It is evident that this terrible revolution, violating all that was dearest and most sacred in Egyptian life and traditions, must have been a devastating experience for the young sovereign. Thebes became an impossible place of residence. His father's palace was disfigured by his own hand and the towering pylons and obelisks of Karnak and Luxor were a continual reminder of all that his fathers had contributed to the glory of Amon and the old gods. He therefore determined to forsake the capital and imperial residence of his ancestors. In each of the three great divisions of the empire, Egypt, Nubia and Asia, he built a city consecrated to Aton, and in the Egyptian Aton city he took up his own residence. He chose as its site a spacious bay in the Nile cliffs about 160 m. above the Delta and nearly 300 m. below Thebes. He called it "Akhetaton," which means "Horizon of Aton" and it is known in modern times as Tell el-Amarna. The city thus established was designated as the real capital of the empire. In the sixth year of his reign and shortly after he had changed his name, we find the young king living in his new residence.

The evidence indicates that all that was devised and done in the new city and in the development and propagation of the Aton faith, was the work of the king himself. Everything bears the stamp of his individuality. The men about him must have been irresistibly swayed by his unbending will, for he was evidently not one to stop half way. But Ikhnaton understood enough of the old policy of the Pharaohs to know that he must hold his party by tangible rewards, and his leading followers enjoyed liberal bounty at his hands. Thus one of his priests of Aton and at the same time his master of the royal horse, named Eye, who had by good fortune happened to marry the childhood nurse of the king, states in his tomb inscriptions: "He doubles to me my favours in silver and gold." The commander of Ikhnaton's army likewise says: "He hath doubled to me my favours like the num-

bers of the sand. I am the head of the officials, at the head of the people; my lord has advanced me because I have carried out his teaching, and I hear his word without ceasing. My eyes behold thy beauty every day, O my lord, wise like Aton, satisfied with truth. How prosperous is he who hears thy teaching of life!" Although there probably was a nucleus of men who really appreciated the ideal aspects of the king's teaching, such inscriptions make it evident that many were not uninfluenced by "the loaves and the fishes."

A beautiful cliff-tomb hewn in the eastern cliffs by royal craftsmen at the king's command was the Pharaoh's most welcome demonstration of favour to each one of his followers. The walls of such a tomb chapel bore fresh and natural pictures from the life of the people in Akhetaton, the new capital, particularly incidents in the life of the dead man, and preferably his intercourse with the king. Thus the city of Akhetaton is now better known to us from its cemetery than from its ruins.

Throughout these tombs, both in relief and inscription, the nobles take delight in reiterating the intimate relation between Aton and the king. Over and over again they show the king and the queen standing together under the disk of Aton, whose enveloping rays terminating in hands, descend and embrace the king's figure. The nobles constantly pray to the god for the king, saying that he "came forth from thy rays," or "thou hast formed him out of thine own rays"; and interspersed through their prayers were numerous current phrases of the Aton faith, which had now become conventional, replacing those of the old orthodox religion which it must have been very awkward for them to cease using. On State occasions instead of the old stock phrases, with innumerable references to the traditional gods, every noble who would enjoy the king's favour was evidently obliged to display his familiarity with the Aton faith by a liberal use of these new allusions. The source of such phrases was really the king himself, and something of the "teaching" whence they were taken, so often attributed to him, is preserved in these "Amarna tombs," as we now commonly call them.

Hymn to Aton.—Among the fragments of the Aton faith which have survived in these tombs are two hymns to Aton, the longer and finer of which is worthy of being known in modern literature. It was probably written by the king himself. In the following translation the effort has been chiefly to furnish an accurate rendering. The headings of the strophes are insertions by the present writer, intended to make clear the arrangement of the subject matter, especially striking because it is identical with that in Psalm civ. of the Old Testament, which is many centuries later.

NIGHT

When thou settest in the western horizon of the sky,
The earth is in darkness like the dead;
They sleep in their chambers,
Their heads are wrapped up,
Their nostrils are stopped,
And none seeth the other,
While all their things are stolen,
Which are under their heads,
And they know it not.
Every lion cometh forth from his den,
All serpents, they sting.
Darkness . . .
The world is in silence,
He that made them resteth in his horizon.

DAY AND MAN

Bright is the earth when thou risest in the horizon.
When thou shinest as Aton by day
Thou drivest away the darkness.
When thou sendest forth thy rays,
The Two Lands (Egypt) are in daily festivity,
Awake and standing upon their feet
When thou hast raised them up.
Their limbs bathed, they take their clothing,
Their arms uplifted in adoration to thy dawning
(Then) in all the world they do their work.

DAY AND THE ANIMALS AND PLANTS

All cattle rest upon their pasturage,
The trees and the plants flourish,
The birds flutter in their marshes,

Their wings uplifted in adoration to thee.
All the sheep dance upon their feet,
All winged things fly,
They live when thou hast shone upon them.

DAY AND THE WATERS

The barques sail up-stream and down-stream alike.
Every highway is open because thou dawnest.
The fish in the river leap up before thee.
Thy rays are in the midst of the great green sea.

CREATION OF MAN

Creator of the germ in woman,
Maker of seed in man,
Giving life to the son in the body of his mother,
Soothing him that he may not weep,
Nurse (even) in the womb,
Giver of breath to animate every one that he maketh!
When he cometh forth from the womb . . . on the day of his birth,
Thou openest his mouth in speech,
Thou suppliest his necessities.

CREATION OF ANIMALS

When the fledgling in the egg chirps in the shell
Thou givest him breath therein to preserve him alive.
When thou hast brought him together (?)
To (the point of) bursting it in the egg,
He cometh forth from the egg
To chirp with all his might (?).
He goeth about upon his two feet
When he hath come forth therefrom.

THE WHOLE CREATION

How manifold are thy works!
They are hidden from before (us),
O sole God, whose powers no other possesseth.
Thou didst create the earth according to thy heart
While thou wast alone:
Men, all cattle, large and small,
All that are upon the earth,
That go about upon their feet;
(All) that are on high,
That fly with their wings.
The foreign countries, Syria and Kush,
The land of Egypt,
Thou settest every man into his place,
Thou suppliest their necessities.
Every one has his possessions,
And his days are reckoned.
The tongues are divers in speech,
Their forms likewise and their skins are distinguished.
(For) thou makest different the strangers.

We may conjecture that this hymn, partially reproduced above, was a fragment from the ritual of Aton as it was celebrated from day to day in the Aton temple at Amarna. Unhappily it was copied in but one tomb; in the others we have a miscellany of current quotations and stock phrases which made up the knowledge of the new faith as it had been apprehended by the scribes and painters who decorated these tombs. It is our misfortune that the fragments of the Aton faith, which have survived to us in the Amarna cemetery, our chief source, have thus filtered mechanically through the indifferent hands and the starved and listless minds of a few petty bureaucrats on the outskirts of a great religious and intellectual movement.

The New Universalism.—Nevertheless in this great hymn the new universalism of the empire finds full expression and the royal singer sweeps his eye from the far-off cataracts of the Nubian Nile to the remotest lands of Syria. He was looking beyond the nationalism which had prevailed for over 2,000 years, and he was consciously endeavouring to displace it by a world religion. Irrespective of race or nationality, he bases the universal sway of God upon his fatherly care of all men alike. He calls Aton "the father and the mother of all that he has made," and the hymn which we have just quoted above is very explicit in its insistence that Aton's fatherly care of all men entirely disregards diversity of speech or difference in colour. To the proud and exclusive Egyptian he points to the all-embracing bounty of the common father of humanity, even placing Syria and Nubia before Egypt as he catalogues the divisions of his empire.

Ikhnaton had gained the conception of a world-lord in two aspects: first, as the creator of the natural world; and second,

as a benevolent father actively concerned for the daily maintenance of all his creatures, even the meanest. His hymns are the earliest known expression of deep emotion in the recognition of divine goodness and benevolence. Mingled with it is an almost ecstatic rapture in the thought of the all-enveloping light in which he saw revealed both the beauty and the goodness of the natural order. It reminds us of Him who bade us "consider the lilies." The picture of the lily-grown marshes, where, as another hymn tells us, the flowers are "drunken" in the intoxicating radiance of Aton, where the birds unfold their wings and lift them "in adoration of the living Aton," where the cattle dance with delight in the sunshine, and the fish in the river beyond leap up to greet the light, the universal light whose beams are even "in the midst of the great green sea"—all this discloses a discernment of the presence of God in nature, and an appreciation of the revelation of God in the visible world such as we find centuries later in the Hebrew psalms, and especially in our own poets since Wordsworth.

While the creative power and the benevolence of his god were very explicitly affirmed by Ikhnaton, our sources do not show us that he had risen from a discernment of the beneficence to a conception of the righteousness in the character of God, nor of his demand for this in the character of men. Nevertheless, there is in Ikhnaton's "teaching," as it is thus fragmentarily preserved in the hymns and tomb-inscriptions of his nobles, a constant emphasis upon "truth" such as is not found before nor since. The king always attached to his name the extraordinary phrase "living in truth," and that this phrase was not meaningless is evident as we discern the character of his daily life.

To him "living in truth" meant sincere acceptance of the daily facts of living in a simple and unconventional manner never before seen in the life of a sovereign and quite impossible of harmonization with the outward pomp and splendour of an oriental emperor. For him what *was* right, and its propriety was evident by its very existence. Even in public he divested his daily round of those outward and formal observances which his royal ancestors had observed for 2,000 years. Thus, his family life was open and unconcealed before the people, even in intimate manifestations of family affection. He took the greatest delight in his children and appeared with them and the queen their mother on all possible occasions as if he had been but the humblest scribe in the Aton-temple. He had himself depicted on the monuments while enjoying the most familiar and unaffected intercourse with his family, and when he drove in his chariot to the temple to carry on its formal service, the queen and the daughters she had borne him likewise drove thither through the acclaiming multitudes and shared with the king the temple service. All that was natural was to him true, and he never failed practically to exemplify this belief, however radically he was obliged to disregard tradition.

Effect of the Revolution on Art.—These revolutionary changes in religion and in the position and character of the head of the State were not confined to theology, statecraft or palace proprieties. They unavoidably affected also the art of the time, and it was the intention of Ikhnaton to modify art in accordance with his regard for "truth." His chief sculptor, Bek, appended to his title the words, "whom his majesty himself taught." It is evident that the artists of Ikhnaton's court were taught by him to make the chisel and the brush tell the story of what they actually saw. The result was a simple and beautiful realism that saw more clearly than any art had ever seen before. They caught the instantaneous postures of animal life; the coursing hound, the fleeing game, the wild bull leaping in the marsh; for all these belonged to the "truth" in which Ikhnaton lived. The exalted divinity which for untold centuries had invested the Pharaoh's person with inviolable sacredness was stripped away without hesitation. Ikhnaton's artists represented him as they saw him, in attitudes of parental affection as he fondled his little daughters, or even as the object of the wifely solicitude of his queen as she stands in his presence in affectionate concern for his needs. Such is the lovely scene on the back of the famous palace chair, preserved to us in the tomb of Tutankhamun. For the first time in

the history of art the subject of a great composition was a human relationship, and to depict it the artists of the day shook off the shackles of immemorial tradition. The monuments of Egypt and even the furniture and equipment of daily life bore what they had never borne before, a Pharaoh depicted in the natural and unaffected relations of life, and completely liberated from the rigid and conventional posture demanded by both the traditions of court propriety and by the venerable teachings of the State theology regarding the divinity of the sovereign. It is in this extraordinary art, which we commonly call the "Amarna school" or "Amarna art," that the revolution of Ikhnaton is most clearly disclosed as the earliest known age of spiritual emancipation.

Loss of the Empire.—A man wholly absorbed in a revolution like this found little time or inclination to devote any attention to the critical state of the empire. For three generations the royal house of Egypt had stood in close relations to the kings of Western Asia, and especially the kings of Mitanni on the Upper Euphrates had given their daughters in marriage to the Pharaoh. Supported by such alliances Ikhnaton failed to appreciate the gravity of the new movements which were transforming the political situation in Western Asia. In the north the expanding power of the Hittites gradually absorbed all the Pharaoh's vassal States in Syria; while in the south, *i.e.*, in Palestine, the incoming mercenary bands of nomads were steadily taking possession of Palestine, which the Pharaohs had held for centuries. It was this movement of nomadic hordes from the desert toward a settled life in the Palestinian towns, which carried the Hebrews into Palestine. At Akhetaton, the new and beautiful home of the Aton faith, the temple of Aton resounded with hymns to the new god of the empire, while the empire itself was no more.

The storm which had thus broken over Ikhnaton's Asiatic empire was not more disastrous than that which threatened him in Egypt; but there was no faltering in his steadfast policy. At his command temples of Aton had arisen all over a land which was now convulsed with revolution. Some years after Ikhnaton had disappeared, his son-in-law, Tutankhamun, left the following description of the hopeless situation of Egypt both at home and abroad: "The temples of the gods and goddesses were [desolated] from Elephantine [First Cataract] as far as the marshes of the delta. . . . Their holy places were forsaken and had become overgrown tracts. . . ., their sanctuaries were like that which has never been, and their houses were trodden roads. The land was in an evil pass, and as for the gods, they had forsaken this land. If people were sent to Syria to extend the borders of Egypt, they prospered not at all; if men prayed to a god for succour, he came not; . . . if men besought a goddess likewise, she came not at all."

Opposition to the New Religion.—Ikhnaton had endeavoured to exterminate some of the most cherished beliefs of the people, especially those regarding the hereafter. Throughout the entire cemetery of his new capital not a single tomb contains the name of Osiris, upon whom every Egyptian, following the faith and practice of his ancestors, expected to depend for protection and guidance through the terrible fears and dangers that beset the dead in the world beyond the grave. This attempted banishment of Osiris must have aroused the fiercest opposition among the people. Eighteen hundred years after Ikhnaton's revolution, the Christian emperor, Theodosius, endeavoured to banish from Egypt the old pagan gods of the people, in an effort to introduce exclusively the God of the Christians. Long after the death of Theodosius the old gods of Egypt continued nevertheless to be worshiped by the people of Upper Egypt. What the power of the Roman emperor failed to accomplish could not of course be attained under much less favourable circumstances by Ikhnaton. The Aton-faith remained but the cherished theory of the idealist Ikhnaton and a little court circle surrounding his person; it never really became the religion of the people.

To the secret resentment and opposition of the people we must also add the dangerous activities of the dispossessed priesthoods, especially the politically powerful former priests of Amon, the old State god. Even more dangerous was the disaffection and discontent among the leaders of the army as they beheld the

Egyptian empire in Asia falling to pieces for lack of effective military intervention. One of these leaders indeed, an officer named Haremhab who had long been a favoured partisan of Ikhnaton, not only contrived to win the support of the military class, but also gained the favor of the priests of Amon, who were of course looking for just such a man. Thus both the people and the priestly and military groups alike were united in plans for the overthrow of the hated dreamer in the palace of the Pharaohs, of whose thoughts they understood so little, and who incensed them with the teaching that both the Asiatics and the Egyptians were all children of the same kindly Father. In this dangerous situation, having no son to succeed him, he gave his eldest daughter in marriage to one of his favourites, and needing support, appointed his son-in-law as co-regent with himself. His position seems to have been complicated by family troubles in these closing days, and we find the name of his queen expunged from some of the family monuments at Amarna. He survived but a short time after arranging the co-regency and about 1358 B.C., in the 17th year of his reign, when he was probably not yet 30 years of age, he passed away.

It must be admitted that Ikhnaton pursued his aims with fatuous blindness and feverish fanaticism regardless of the destructive costs. There is something hectic and abnormal in this extraordinary man, suggesting a mind which may even have been diseased. Some question has been raised regarding the identity of the body found in his coffin; but it should be noted that the skull found with this body is one of the largest human crania ever found. However much we may censure him for the loss of his empire, however much we may condemn the fanaticism with which he pursued his aim, it must be recognized that there died with him a spirit such as the world had never seen before—a brave soul, undauntedly facing and opposing the momentum of century long tradition, in which it had never occurred to any mind before his to do anything but thoughtlessly acquiesce. He was the first of the long line of revolvers against tradition and thoughtless acceptance of the past. He stepped out of the long line of conventionally colourless Pharaohs that he might disseminate ideas far beyond and above the capacity of his age to understand. Among the Hebrews, seven or eight hundred years later, we look for such men. We must look back upon him to-day not only as the world's first idealist and the world's first *individual*, but also as the earliest monotheist and the first prophet of internationalism—the most remarkable figure of the Ancient World before the Hebrews.

IKI, an island belonging to Japan, lying off the north-western coast of Kyushu, in 33° 45' N. lat. and 129° 40' E. long. It has a circumference of 86 m., an area of 51 sq.m., and a population of c. 50,000. The island is, for the most part, a tableland about 500 ft. above sea-level. The anchorage is at Gonoura, on the south-west. A part of Kublai Khan's Mongols landed at Iki when about to invade Japan in the 13th century, for it lies in the direct route from Korea to Japan via Tsushima.

ILAGAN, a municipality (with administration centre and 57 barrios or districts), and capital of the province of Isabela, Luzon, Philippine Islands, on an elevated site at the confluence of the Abuluan and Cagayan rivers, about 200 m. N.N.E. of Manila. It was formerly included in the province of Nueva Ecija. Pop. (1918), 23,279. The surrounding country is the largest tobacco-growing region in the Philippines. Considerable corn is also raised. In 1918, it had 7 manufacturing establishments with output valued at 44,900 pesos. Of the 21 schools, 19 were public. The language spoken is Ibanag.

ILCHESTER, market town, Somersetshire, England, in the valley of the river Ivel or Yeo, 5 m. N.W. of Yeovil. Pop. (1921) 449. Ilchester (*Cair Pensavelcoit, Ischalis, Ivelcestre, Yevelchester*) was a fortified British settlement, and later a military station of the Romans, on the Fosse Way. Its importance continued in Saxon times, and in 1086 it was a royal borough with 107 burgesses. In 1180 a gild merchant was established, and the county gaol was completed in 1188. Henry II. granted a charter, confirmed by John in 1203, which gave Ilchester the same liberties as Winchester, and its bailiffs are mentioned before 1230. The borough was incorporated in 1556. Ilchester was the centre of the county administration from the reign of Edward III. until the 19th century, when the change from road to rail travelling completed the decay of the town, and the corporation was abolished in 1886. Parliamentary representation began in 1298, and the town continued to return two members until 1832. The Wednesday market dates from before the Conquest. It possesses almshouses founded in 1426 and an ancient mace of the former corporation.

ÎLE-DE-FRANCE, an old district of France, forming a kind of an island, bounded by the Seine, the Marne, the Beuvronne, the Thève and the Oise. In this sense the name is not found in written documents before 1429; but in the second half of the 15th century it designated a wide military province of government, bounded on the north by Picardy, on the west by Normandy, on the south by Orléanais and Nivernais, and on the east by Champagne. Its capital was Paris. From the territory of Île-de-France, were formed under the Revolution the department of the Seine, together with the greater part of the Seine-et-Oise, Seine-et-Marne, Oise and Aisne, and a small part of Loiret and Nièvre. (The term Île-de-France is also used for Mauritius, *q.v.*)

See A. Longnon, "L'Île-de-France, son origine, ses limites, ses gouverneurs," in the *Mémoires de la Société de l'histoire de Paris et de l'Île-de-France*, vol. i. (1875).

ILERDA, CAMPAIGN OF (49 B.C.). On Dec. 17 Julius Caesar, the leader of the democratic party in the Second Civil War, crossed the Rubicon and in sixty days was master of Italy. As he failed however to shut Pompey up in Brundisium, this general sailed for Dyrrachium. The problem which now confronted Caesar was a complex one. He was without a fleet, and though the aristocratic party was no longer in the ascendant, Italy was still at Pompey's mercy because he could cut her off from her grain supplies in Egypt, Sicily and Sardinia. In Greece Pompey's resources were great both in men and money, and that he would there increase the strength of his already powerful army was certain. In Spain he still possessed seven legions who threatened Gaul, and might be brought to Italy. Caesar determined to strike at weakness rather than at strength. Abandoning any idea of moving through Illyria against Pompey, and trusting that the dilatory nature of his antagonist would enable him to gain time, on March 9, 49 B.C., he left Rome for Massilia with the intention of disposing of Pompey's legions in Spain before he turned on Pompey himself.

Pompey's generals in Spain were Afranius and Petreius, their total forces numbering some 70,000 men, to which Caesar could oppose but 40,000, including three legions under Fabius which he forthwith sent from Narbo across the Pyrenees. At Ilerda on the river Sicoris which flows into the Ebro, Fabius found Afranius strongly encamped, and entrenched himself within three miles of him. Shortly after, Caesar arriving, active operations were at once begun by moving the camp close up to the enemy's so as to restrict the movement of his foragers. In order to cut Afranius off from the bridge at Ilerda, Caesar attempted to occupy a ridge which lay between the camps, but the XIV. legion was driven back. Counter-attacking with the IX. legion he drove a large party of the enemy into Ilerda and then tried to assault this city by forcing his way up a ravine; here he nearly met with a disaster, and had much difficulty in extricating himself.

Two days after this battle, which reflected no great credit on Caesar, his bridges over the Sicoris were swept away by a flood, and his communications with Gaul severed; worse still, his convoys could no longer reach him. Learning that he was expecting

a large convoy, Afranius crossed the bridge at Ilerda with three legions and all his cavalry and attacked it. The attack, however, failed, and Caesar building a boat bridge 22 miles north of his camp enabled his convoy to cross, and his cavalry to attack Afranius's foragers.

In order further to restrict his enemy, by running the river into a number of artificial channels he created a ford near his camp

PLAN OF CAMPAIGN AT ILERDA, 49 B.C., WHERE JULIUS CAESAR FORCED HIS ENEMY TO RETIRE WITHOUT GIVING BATTLE

which forced the Pompeians to transport two legions over the Sicoris to protect their communications, and then, on June 23, still holding the bridge they crossed their whole army over to the left bank, and set out towards the Ebro. Caesar having now dislodged his enemy, his next step was not to defeat him but to force him to surrender. Not only would this save him casualties but augment his army, as all prisoners would be incorporated in it. He wished to gain his object by manoeuvring rather than by fighting. Sending his Gallic cavalry over the ford, these nimble horsemen greatly impeded the enemy's march, and gained time for Caesar to cross his infantry. The manoeuvres now carried out were remarkable, and are shown on the plan. (1) Caesar rapidly followed Afranius and forced him to form front; (2) Afranius retired skirmishing, Caesar following; (3) Afranius decided to retire on Octogesa, Caesar pretending to withdraw, and Afranius made towards the defile; (4) Caesar counter-marched and cut him off from the defile; (5) Afranius reverted to retirement on Octogesa; Afranius was now strategically beaten, and Caesar could have annihilated him but refused to do so; (6) Afranius made for the Sicoris to obtain water; (7) Caesar headed him off; (8) Afranius attempted to regain Ilerda, but was forced to surrender on July 2. The result of these masterly and bloodless manoeuvres were, that not only did Pompey lose Spain but also his oldest and best legions, and simultaneously Caesar at little loss added immensely to his own strength. Of their kind the manoeuvres of Ilerda have seldom been rivalled and never surpassed. See PHARSALUS.

(J. F. C. F.)

ILETSK, a settlement in the province of Orenburg in the R.S.F.S.R., in 51° 10' N. and 55° E., 48 m. S. of the town of Orenburg by the railway to Tashkent, near the Ilek river, a tributary of the Ural. Pop. (1926) 11,058. Rock-salt is worked here to the extent of about 100,000 tons annually. The place is resorted to for its salt, mud and brine baths, and its *koumiss* cures.

ILFELD, a town in the Prussian province of Hanover, at the south foot of the Harz, at the entrance to the Böhrethal, 8 m. N. from Nordhausen by the rail to Wernigerode. Pop. 1,925. Ilfeld, as a town, dates from the 14th century, when it sprang

up round a Benedictine monastery. It manufactures parquet-flooring, paper and plaster of Paris, and has coal mines.

ILFORD (GREAT ILFORD), an urban district of Essex, England, on the Roding, 7 m. E.N.E. of London by rail. Pop. (1901) 41,234; (1921) 85,194. A portion of Hainault Forest lies within the parish. The hospital of St. Mary and St. Thomas, founded in the 12th century as a leper hospital, now contains almshouses and a chapel. Claybury Hall is a mental hospital (1893) of the London County Council. There are large photographic material works and paper-mills. **LITTLE ILFORD** is a parish on the opposite (west) side of the Roding. The church of St. Mary retains Norman portions.

ILFRACOMBE, a watering-place of Devonshire, England, on the Bristol channel, 225 m. W. by S. of London by rail. Pop. of urban district (1926) 11,772. In the late 13th century it obtained a grant for holding a fair and market, and in the reign of Edward III. it supplied six ships and 96 men for the expedition against Calais. During the Civil War, it was in 1644 captured by the Royalists, but in 1646 it fell into the hands of Fairfax. The old town is built on the cliffs above the harbour. Behind it rise the terraces of a more modern town. Wooded heights form a semi-circle round the town, which is protected from sea winds by Capstone hill. The restored church of Holy Trinity dates originally from the 12th century.

ILG, PAUL (1875-), Swiss poet and dramatist, was born at Salenstein (Thurgau) on March 14, 1875. He was engaged in business down to 1899; since when he has been an author and editor. Among his chief novels are *Der Lebensdrang* (1906), *Der Landstörtzer* (1909), *Das Menschlein Matthias* (1913), *Der Starke Mann* (1916) and *Probus* (1922). He has also written the dramas *Der Führer* (1919), *Der Mann Gottes* (1924), *Der Kampf mit dem Drachen* (1927) and *Ga Llama* (1928). Ilg belongs to the realistic school, and his writing is strong and direct.

ILHAVO, a Portuguese seaport on the lagoon of Aveiro (*q.v.*). Pop. (1920) 12,691. Ilhavo is inhabited chiefly by fishermen, but has a celebrated manufactory of glass and porcelain, the Vista-Alegre, at which the art of glass-cutting has reached a high degree of perfection. Salt is largely exported. Ilhavo is celebrated for the beauty of its women.

ILI, a river of Central Asia, flowing for the greater part of its course through the Kazakstan A.S.S.R. The head-stream, called the Tekez, rises at an altitude of 11,600 ft. east of Lake Issyk-kul in 82° 25' E. and 43° 23' N., on the west slopes of mount Kashatur. At first it flows eastward and north-eastward, until, after emerging from the mountains, it meets the Kungez, and then, assuming the name of Ili, it turns westwards and flows between the Temurlik-tau and Trans-Ili or Kungei Ala-tau mountains on the south and the Borokhoro and Talki ranges on the north for about 300 m. to Iliysk. The valley between 79° 30' and 82° E. is 50 m. wide, and the portion above the town of Kulja (Old Kulja) in east Turkistan is fertile and populous, Taranchi villages following each other in rapid succession, and the pastures being well stocked with sheep, cattle and horses. At Iliysk the river turns north-west, and after traversing a region of desert and marsh falls by at least seven mouths into the Balkash lake, the first bifurcation of the delta taking place about 115 m. up the river. But it is only the southern arm of the delta that permanently carries water. The total length of the river is over 900 m. From Old Kulja to New Kulja the Ili is navigable for at most only two and a half months in the year, and even then considerable difficulty is occasioned by the shoals and sandbanks. From New Kulja to Iliysk (280 m.) navigation is easy when the water is high, and practicable even at its lowest for small boats. At Iliysk there is a ferry on the road from Kopal to Alma-Ata (Vyernyi). The principal tributaries of the Ili are the Kash, Chilik and Charyn. Many streams flow towards it from the mountains on both sides, but most of them are used up by the irrigation canals and never reach their goal. The wealth of coal in the valley is said to be great, and when the Chinese owned the country they worked gold and silver with profit. Fort Ili or Iliysk, a modern Russian establishment, must not be confounded with Ili, the old capital of the Chinese province of the same

name. The latter, otherwise known as Hoi-yuan-chen, New Kulja (Gulja), or Manchu Kulja, was formerly a city of 70,000 inhabitants, but now lies completely deserted. Old Kulja, Tatar Kulja or Nin-yuan, is now the principal town of the district. The Chinese district of Ili formerly included the whole of the valley of the Ili river as far as Issyk-kul, but now only its upper part. It belongs administratively to the province of Sinkiang or East Turkistan. (See KULJA.)

ILION, a village of Herkimer county, N.Y., U.S.A.; 12 m. S.E. of Utica, on the Mohawk river and the State Barge canal. It is served by the New York Central and the West Shore railways. The population in 1925 was 10,426. It has notable manufactures, including the Remington typewriters, cash registers and firearms, as well as office furniture. The factories employ over 5,600 persons and their annual output is valued at nearly \$28,000,000. As early as 1816 a store was established here, but permanent settlement began on the completion of the Erie canal in 1825. The village was known by several different names in its earlier years. It was incorporated in 1852. In 1828 Eliphalet Remington (1793-1861) established a small factory for making firearms. He invented, and with the assistance of his sons (Philo, Samuel, and Eliphalet) improved the famous Remington rifle, which was used in great quantities by the U.S. army and adopted by several foreign governments. In 1856 the company began making farm tools, in 1870 sewing-machines, and in 1874 typewriters.

ILIPA, BATTLE OF, 206 B.C. This was the culminating battle of the campaigns by which Publius Cornelius Scipio (*q.v.*), afterwards named Africanus, overthrew the Carthaginian power in Spain, and thereby paved the way for his subsequent campaign in Africa which ended in the defeat of Hannibal at Zama (*q.v.*) and the capitulation of Carthage. In military history Ilipa ranks with Gaugamela and Cannae as one of the supreme tactical masterpieces in the military history of the ancient world, and indeed outshines any as an example of a victory ensured by the dislocation of thought and will produced in the mind of one commander by the other before even the fighting troops came into contact. After suffering a series of defeats since Scipio's opening seizure of Cartagena (*q.v.*) in the spring of 206 B.C. the Carthaginians made their last great effort. Hasdrubal Gisco, encouraged by Mago, Hannibal's brother, raised and armed fresh levies, and with an army of 70,000 foot, 4,000 horse and 32 elephants marched north to Ilipa (or Silpia), which was not far from where Seville stands to-day. Scipio moved south from Tarraco to meet the

Carthaginians, collecting auxiliaries on his way. Advancing to the neighbourhood of Ilipa with a total force, Romans and allies, of 45,000 foot and 3,000 horse, he came in sight of the Carthaginians, and encamped on certain low hills opposite them. It deserves notice that his advance was on a line which, in the event of victory, would cut them off from the nearest road to Gades, this road running along the south bank of the Baetis River.

The two camps lay facing each other across the valley between the two low ridges. For several successive days Hasdrubal led his army out and offered battle. On each occasion Scipio waited

until the Carthaginians were moving out before he followed suit. Neither side, however, began the attack, and towards sundown the two armies, weary of standing, retired to their camps—the Carthaginians always first. One cannot doubt, in view of the upshot, that on Scipio's side the delay had a special motive. On each occasion also the legions were placed in the Roman centre opposite to the Carthaginian and African regulars, with the Spanish allies on the wings of each army. It became common talk in the camp that this order of battle was definite, and Scipio waited until this belief had taken firm hold.

Then he acted. He had observed that the Carthaginians made their daily advance at a late hour, and had himself purposely waited still later, to fix this habit on his opponent's mind. Late in the evening he sent orders through the camp that the troops should be fed and armed before daylight, and the cavalry have their horses saddled. Then, while it was scarcely yet daylight, he sent on the cavalry and light troops to attack the enemy's outposts, and himself followed with the legions. This was the first surprise change, and its effect was that the Carthaginians, caught napping by the onset of the Roman cavalry and light troops, had to arm themselves and sally forth without a meal. It further ensured that Hasdrubal would have no time to alter his normal disposition even should the idea occur to him; for the second surprise change was that Scipio reversed his former order of battle, and placed the Spanish in his centre and the legions on the wings. The Roman infantry made no attempt to advance for some hours, the reason being Scipio's desire and design to let his hungry opponents feel the effects of their lost breakfast. There was no risk to his other surprise change by so doing, for once drawn up in order of battle, the Carthaginians dared not alter their array in face of a watchful and ready opponent.

It was about the seventh hour when he ordered the line to advance, but the Spanish centre only at a slow pace. On arriving within 800 yards of the enemy, he himself, leading the right wing, wheeled to the right, and made an oblique advance outwards. The left wing executed a similar movement. Advancing rapidly, so that the slow-moving centre was well refused, the Roman infantry cohorts wheeled successively into line as they neared the enemy's line, and fell directly on the enemy's flanks, which but for this manoeuvre would have overlapped them. While the heavy infantry thus pressed the enemy's wings in front, the cavalry and light infantry, under orders, wheeled outwards again, and, sweeping round the enemy's flanks, took them in enfilade. This convergent blow on each wing, sufficiently dislocating because it forced the defenders to face attack from two directions simultaneously, was made more decisive in that it fell on the Spanish irregulars. To add to Hasdrubal's troubles, the cavalry flank attacks drove his elephants, mad with fright, in upon the Carthaginian centre, spreading confusion. All this time the Carthaginian centre was standing helplessly inactive, unable to help the wings for fear of attack by Scipio's Spaniards, who threatened it without coming to close quarters. Scipio's calculation had enabled him to "fix" the enemy's centre with a minimum expenditure of force, and thus to concentrate the maximum for his decisive double manoeuvre.

Hasdrubal's wings destroyed, the centre, worn out by hunger and fatigue, fell back, at first in good order; but gradually under relentless pressure they broke up and fled to their entrenched camp. A drenching downpour, churning the ground in mud under the soldiers' feet, gave them a temporary respite and prevented the Romans storming the camp on their heels. During the night Hasdrubal evacuated his camp, but as Scipio's strategic advance had placed the Romans across the line of retreat to Gades, Hasdrubal was forced to retire down the western bank towards the Atlantic. Nearly all his Spanish allies deserted him.

Scipio's light troops were evidently alive to the duty of maintaining contact with the enemy, for he got word from them as soon as it was light of Hasdrubal's departure. He at once followed them up, sending the cavalry ahead, and so rapid was the pursuit that, despite being misled by guides in attempting a short-cut to get across Hasdrubal's new line of retreat, the cavalry and light infantry caught him up. Harassing him continuously, by attacks

in flank or in rear, they forced such frequent halts that the legions were able to come up. "After this it was no longer a fight, but a butchering as of cattle," till only Hasdrubal and 6,000 half-armed men escaped to the neighbouring hills, out of 70,000 odd who had fought at Ilipa.

Military history contains no more classic example of generalship than this battle of Ilipa. Frederick's "oblique order" appears immature beside Scipio's double oblique manoeuvre and envelopment, which effected a crushing concentration of strength against weakness while the enemy's centre was surely "fixed." Scipio left the enemy no chance for the change of front which cost Frederick so dear at Kolin. Masterly as were his battle tactics, still more remarkable perhaps were the decisiveness and rapidity of their exploitation, which had hardly an equal in military history until Napoleon came to develop the pursuit as the vital complement of battle and one of the supreme tests of generalship. (B. H. L. H.)

ILKESTON, market town, municipal borough, Ilkeston parliamentary division, Derbyshire, England, 9 m. north-east of Derby on the L.M.S. and L.N.E. railways. Pop. (1921) 32,266. It is situated on a hill commanding fine views of the Erewash valley. The church of St. Mary is Norman and Early English, and has a fine chancel screen (13th century). The manufactures are principally hosiery, lace and various kinds of stoneware; coal and iron are wrought in the neighbourhood. An alkaline mineral spring was discovered in 1830. The town is mentioned in Domesday, obtained a grant for a market and fair in 1251, and received its charter of incorporation in 1887.

ILKLEY, an urban district in the West Riding of Yorkshire, England, 16 m. N.W. from Leeds on the L.M.S. and L.N.E. railways, in Middle Wharfedale and extending to Ilkley moor. Pop. (1921), 9,098. It is a health resort and has several hydropathic establishments. The remains of Bolton abbey lie in the Wharfe valley 5 m. above Ilkley. Camden was the first authority to recognize Ilkley as a Roman site, and associated it with *Olicana*. Little excavation work and few discoveries were made until the 19th century, when Roman objects were found. A systematic excavation of the fort began in July 1919. Much of the site has been destroyed since Roman times. From the structure of the rampart and from finds from deep levels, it is inferred that the fort was established before the end of the 1st century and that a civil settlement sprang up around it. Occupation continued, with breaks, into the 4th century, but the exact date of the final withdrawal of Roman garrisons is still in dispute.

ILL, a river of France, entirely within the departments of Bas-Rhin and Haut-Rhin. It rises on a north foothill of the Jura, south-west of Basel, and flows north-north-east, parallel with the Rhine, which it enters from the left, 9 m. below Strassburg. Its course lies for the most part through low meadowland; and the stream, which is 123 m. long, receives numerous small affluents, which pour out of the short narrow valleys of the Vosges. It is navigable from Ladhof near Colmar to its confluence with the Rhine, a distance of 59 m. It is on this river, and not on the Rhine, that the principal towns of Upper Alsace are situated, e.g., Mulhouse, Colmar, Schlestadt and Strasbourg. The Ill feeds two important canals, the Rhine-Marne canal and the Rhine-Rhone canal, both starting from the neighbourhood of Strasbourg.

ILLAWARRA, a fertile district of New South Wales, Australia, extending from about 33 m. S. of Sydney, along the coast southwards for 40 m. to Shoalhaven. It is thickly populated, and supplies Sydney with the greater part of its dairy produce. There are also numerous collieries, and iron ore, fireclay and freestone are plentiful. The Illawarra Lake, a salt lagoon, 9 m. long and 3 m. wide, is encircled by hills and is connected with the sea by a narrow channel; quantities of fish are caught and wild fowl are abundant along its shores. The chief towns in the district are Bulli, Wollongong, Kiama and Geringong.

ILLE-ET-VILAINE, a maritime department of north-western France, formed in 1790 out of the eastern part of the old province of Brittany. Pop. (1926) 561,688. Area 2,699 sq.m. It is bounded N. by the English Channel, the Bay of St. Michel and the department of Manche; E. by Mayenne; S. by Loire-

Inférieure; and W. by Morbihan and Côtes-du-Nord. The department consists of the basin of the upper Vilaine, with those of its tributaries (all navigable), the Ille from the north, the Seiche from the east, and the Meu from the west, and the coastland north of the low watershed from the estuary of the Rance on the west to that of the Couesnon on the east. The Vilaine is navigable as far north as Rennes, which is connected by canal via the Ille with Evran on the Rance. The rich Marais de Dol, protected by dykes from the sea, occupies most of the north coastal plain. The coast is rocky and dangerous. The climate is oceanic, temperate and rainy, with fogs in spring and autumn. The soil, originally poor, has been improved by the use of artificial manure. Cereals are grown, chiefly wheat, buckwheat, oats and barley. Potatoes, beet-root, early vegetables, flax and hemp are also largely grown, and tobacco is cultivated in the arrondissement of St. Malo. Orchards are abundant, especially near Dol. Stock-raising and dairying are important. Lead mines and quarries of slate, granite, etc., are worked. There are boat-building yards, iron and copper foundries and forges, and a widespread tanning industry. Sail-cloth, rope, pottery, boots and shoes (Fougères), farming implements, paper and furniture are also made. The chief ports are St. Malo and St. Servan. Fishing is very active on the coast, and St. Malo, St. Servan and Cancale send fleets to the Newfoundland codbanks. There are also important oyster-fisheries in the Bay of St. Michel, especially at Cancale. Dinard is the chief of a group of fashionable bathing-resorts. Exports include agricultural products, butter, mine-posts and dried fish; imports, live-stock, coal, timber, building materials and wheat. The department is served by the Ouest-Etat railway. Ille-et-Vilaine is divided into the arrondissements of Fougères, St. Malo, Redon and Rennes, and it consists of 43 cantons and 360 communes. The chief town is Rennes, which is the seat of an archbishop and of a court of appeal, headquarters of the X. army corps, and the centre of an académie (educational division).

ILLEGITIMACY, the state of being of illegitimate birth (from Lat. *illegitimus*, not in accordance with the law, hence born out of wedlock). Illegitimacy may be measured in various ways, the most common being by stating the proportion of illegitimate to total births. Another method, claimed as being a better one, is to relate illegitimate births to the total unmarried, widowed and divorced women of conceptive age in the population under review. The superiority of this latter method is very doubtful, for it is difficult to say what accurate conclusions can be drawn from it. Were illegitimacy an index of either morality or continence in any given community this second method would have a decided value, but no one who has studied the subject would be likely to advance such a claim. A fall in the illegitimate rate calculated in either way may merely indicate a spreading familiarity with the use of contraceptives. By relating the illegitimate to total births we do get a reliable measure of the contribution made to the population by the "unmarried mother," and consequently of the proportion of the population which is of illegitimate birth.

Factors Affecting.—The factors which are alleged to affect illegitimacy are many and varied, but the evidence in regard to a large proportion is extremely contradictory. Those which may be reckoned to be based upon indisputable statistical evidence are relatively few. The most important of these is undoubtedly habit and custom, or, in other words, the presence or absence of social stigma attached to the unmarried mother or the illegitimate child. If in any country the social status of the unmarried mother or the illegitimate child does not differ materially from that of the wife and her legitimate offspring the rate of illegitimacy will be high, and the greater the social obloquy incurred by bearing an illegitimate child the lower that rate will be. The factor second in importance is the extent of legal disability incurred by parent or offspring; then the existence or non-existence of barriers (legal, social, economic) to early or easy marriage and, finally, the formalities prescribed for subsequent legitimation or the total absence of these. Each one of these has its effect, in varying degree, on the illegitimate rate.

Two other alleged factors are religion and climate, but these

must be reckoned doubtful if not disproven. It is stated, for example, that Roman Catholic countries show a lower rate than those of other cults, and the fact that in Ireland the rate of illegitimacy is little more than half that of England and Wales and about one-third that of Scotland is invariably put forward as a convincing proof. But Roman Catholic Austria had an illegitimate birth-rate three times that of England and Wales and 50% above that of Hungary. On the climatic side, it has been more or less generally accepted that the warmer countries of southern Europe had a higher proportion of illegitimacy. But the highest rates are found in the more northern countries, in Denmark and in Sweden, whilst in Iceland the rate is higher still. Another popular idea is that the great cities have a higher illegitimate rate than the rural districts, but on this point also the available evidence is contradictory. The rural districts of England and Wales have a much higher illegitimate birth-rate than has London, while on the mainland of Scotland the rural rate is considerably above that for the towns. On the other hand, in the Netherlands the proportion of illegitimate to total births rises steadily with the degree of urbanization, being lowest in the towns or villages with fewer than 5,000 inhabitants and highest in the great cities. The same holds good of Finland, where the town rate of illegitimacy is double that of the rural areas.

Variation.—The extent to which illegitimacy prevails in any given country shows relatively slight variations during the course of the last half-century, but the variation from country to country is very wide. Thus in England and Wales the proportion of illegitimate births to 1,000 total births, which was 48 in the quinquennium 1876-1880, was 43 in 1921-25, a decline of 10%. In Scotland the fall in the same period was more marked, being from 85 to 64. In Germany, however, the rate rose from 87 in 1876-80 to 110 in 1921-25, in Sweden from 100 to 145. Here the widest variation in any country is one of 45%. But in the last quinquennium under review the rates in European countries varied from 19 in the Netherlands to 106 in Denmark, 110 in Germany and 145 in Sweden. Going outside Europe, we find within the confines of the British empire an illegitimate birth-rate of about 20 per 1,000 in Ireland and of over 700 per 1,000 in Jamaica. In the following table the rates are given for certain European countries and also for Australia and New Zealand for alternate quinquennia from 1881-85 to 1921-25, the period 1916-20, which was directly affected by the World War, being dealt with separately. In dealing with these rates it must be borne in mind that, where some disability is incurred by illegitimacy, there is an obvious motive for non-registration of such a birth, and that the figures may be affected to some extent by the efficiency or otherwise of the registration system in operation at the time.

TABLE I. *Illegitimate Births per 1,000 Births*

	1881-85	1891-95	1901-05	1911-15	1921-25
England and Wales	48	42	40	43	43
Scotland	83	74	64	72	68
Denmark	100	94	101	114	106
Finland	70	65	65	78	89
France	78	87	88	90	90
Germany	92	91	84	100	110
Italy	76	69	56	47	47
Netherlands	30	31	23	21	19
Norway	81	71	70	69	66
Sweden	102	105	119	155	145
Switzerland	48	46	45	47	38
Australia	39	50	60	55	47
New Zealand	29	38	45	43	45

This table shows clearly that there is no general trend in the illegitimate birth-proportion in the countries shown. England and Wales, Scotland, Germany and Switzerland show declines up to the third quinquennium, Italy to the fourth, the Netherlands and Norway throughout. In Denmark the rise and fall are erratic, in France there is a persistent rise, in Sweden one much more marked up to the end of the fourth, in Australia and in New Zealand a marked rise up to the end of the third period. Comparing the first with the last, we find that in six of the 13 coun-

tries the rate in the last period is lower than in the first, while in the other seven it is higher. England and Wales, Scotland, Italy, the Netherlands, Norway and Switzerland have the maximum rate in 1881-85, Denmark and Sweden in 1911-15, Australia in 1901-05, Finland and Germany in 1921-25.

Influence of the World War.—During the quinquennium 1916-20, the period most directly affected by the war, the proportions of illegitimate to total births in the belligerent countries shown in Table I. were as follows:—England and Wales 54, an increase of 25% over the rate for the preceding quinquennium; Scotland 76, an increase of 5%; Finland 83, an increase of 6%; France 120, an increase of 33%; Germany 113, an increase of 13%; Italy 45, a decrease of 4%; Australia 51, a decrease of 7%; New Zealand 45, an increase of 5%. England and Wales, France and Germany show marked increases in the proportions of illegitimate to total births; in Scotland, Finland and New Zealand the increase is insignificant, while in Italy and Australia there was an actual decrease. The rise in the proportion may, of course, have been due either to an actual increase in the number of illegitimate births or to the fall in illegitimate births being less marked than the general fall in births during this period. To make the position clear, the average annual numbers of the illegitimate births in some of these countries in the three quinquennia 1911-15, 1916-20; 1921-25 are given in Table II.

TABLE II. *Average Number of Illegitimate Births per Annum*

	1911-15	1916-20	1921-25
England and Wales	37,329	40,622	32,694
Scotland	8,608	8,315	7,681
Finland	6,865	6,280	7,049
France			
Germany	177,645	136,923	154,592
Italy			
Australia	7,209	6,462	6,291
New Zealand	1,163	1,077	1,270

In looking at these figures it may be explained that those for France and for Italy are omitted because they deal with different populations, and while rates may be given without departing from substantial accuracy, numbers would prove entirely misleading. Those for Germany for 1921-25 should be increased by some 10% to compensate for the loss of population entailed by the cession of territory to France and Poland; which would bring them up close to the pre-war level. The only case in which an actual increase in the numbers of the illegitimate births is shown is in England and Wales, so that any rise in the proportion of illegitimates in the other countries was due, not to a numerical increase, but to the fact that the proportional decline in illegitimate births was smaller than that for legitimate during the war period. That this was not the case in England and Wales was, presumably, due to the presence of comparatively large numbers of troops from the British dominions.

From the rates shown in the last column of Table I., it would appear that the post-war effects are inconsiderable, the only countries showing any marked increase in the illegitimate rate over that obtaining in the immediate pre-war period being Finland and Germany.

In England and Wales, France and Italy, the rates for these two periods are identical, in Scotland and Australia the latter rate is lower, in New Zealand the rise is too slight to admit of any valid inference being drawn.

United States.—Owing to the fact that in the United States the system of birth registration has been of gradual growth, it has not been possible to give comparative figures as to illegitimacy as in Table I. Of more recent years, however, the figures covering some 70% of the total population are available, and show the position with reliable accuracy. For the triennium 1921-23, the proportion of illegitimate to total births was at the rate of 24 per 1,000. There was, however, a very marked difference for the white and the coloured populations; for the former it was only 14, for the latter 126. In the coloured population, therefore, there were nine illegitimates to one among the whites. The illegitimate proportion in the various States under review varied from

seven in Wyoming to 84 in South Carolina; the difference from State to State being mainly determined by the proportion of the coloured to the white population. The illegitimate proportions in the white population are analysed according to the country of birth of the mother, with the following result.

All white mothers 14 per 1,000 total births.					
Mothers born in United States	16	"	"	"	"
" " " Canada	13	"	"	"	"
" " " Germany	12	"	"	"	"
" " " Gt. Britain	10.5	"	"	"	"
" " " Ireland	10.3	"	"	"	"
" " " Italy	2	"	"	"	"

Possibly the most interesting feature of this analysis is the fact that, under similar social conditions, the rate of illegitimacy is practically identical for mothers born in Great Britain and in Ireland, although the illegitimacy rate for Ireland itself is only about half that of England and Wales and one-third that of Scotland.

Extra-European Rates.—In the European countries with which we have dealt and in those inhabited by European stocks, it is evident that the illegitimates form a comparatively insignificant fraction of the total population. The same remark holds good for Japan as the following figures show:—

Illegitimate Births Per 1,000 Total Births

Japan: 1891-95: 116; 1899-1905: 91; 1921-25: 78.

Here the decline in the proportion of illegitimate to total births has been marked and continuous. A different picture is presented by the Central and South American countries for which the figures are available, these being given in Table III.

TABLE III. *Illegitimate Births to 1,000 Total Births*

Period.	Chile	Period.	Costa Rica	Period.	Cuba	Period.	Ecuador
1903-05	357	1883-85	188	1900-05	342
1913-15	373	1911-13	237	1911-13	237
1921-25	304	1921-25	345

Period.	Mexico	Period.	Panama	Period.	Salvador	Period.	Uruguay
1895-97	376	1899-1905	510	1896-1905	259
1910	423	1912-16	689	1911-13	536	1911-13	251
..	..	1921-25	710	1921-25	590	1921-25	288

It is quite evident from these figures that illegitimacy is looked upon in these countries in a light very different from that in which it is regarded in those peopled mainly by Europeans; as in Jamaica and other of the West Indian islands the population is largely recruited from the unmarried. Indeed, in Salvador and Panama those of legitimate birth constitute the smaller fraction of the population, and in several of the others the proportion of illegitimates shows a rising tendency. (S. DE J.)

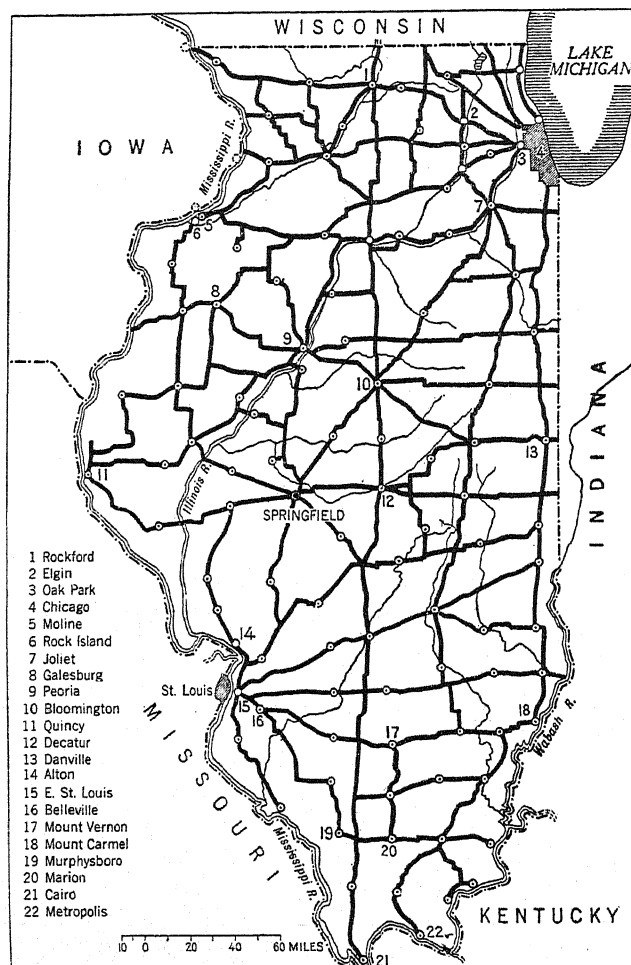

ILLER, a tributary of the Danube. It rises in the Algäuer Alps, flows northward through Upper Bavaria for 103 m., and, after passing Immenstadt and Kempton, joins the Danube near Ulm. (See DANUBE.)

ILLINIUM. In 1926, B. S. Hopkins definitely identified the chemical element of atomic number 61 and gave it this name. In the same year Corke, James and Fogg independently obtained it and measured the lines of its X-ray spectrum. (See RARE EARTHS.) Certain Italian chemists claimed priority in this discovery and named the element florentium (*q.v.*).

ILLINOIS (il'i-noi or il'i-noiz), the Prairie State, one of the north central group of the United States of America, situated between 37° and 42° 30' N. lat. and 87° 35' and 91° 31' W. longitude. It is bounded on the north by Wisconsin, east by Lake Michigan and Indiana, south-east and south by the Ohio river, which separates it from Kentucky, and south-west and west by the Mississippi river, which separates it from Missouri and Iowa. The enabling act of Congress, which provided for the organization of Illinois territory into a State, extended its jurisdiction to the middle of Lake Michigan and the Mississippi river. The

State's greatest length is 379½m. and its extreme width is 211 miles. The total area of the State, exclusive of its Lake Michigan jurisdiction, is 56,630sq.m. of which 56,043sq.m. are land.

Physical Features.—The State, except the extreme southern point, lies wholly in the great prairie region. The southern point touches the Coastal Plain Belt at its northward extension along the Mississippi river. The surface of the State is an inclined

MAP SHOWING THE MAIN ROADS OF ILLINOIS

plane whose general slope is toward the south and south-west. Illinois is the most level State in the Union with the exception of Louisiana and Delaware. The average elevation above sea-level is about 600ft.; the highest elevation is Charles Mound (1,257ft.), on the Illinois-Wisconsin boundary lines, one of a group of hills in the north-western part of the State, in Jo Daviess, Stephenson, Winnebago, Boone and McHenry counties. An elevation from 15 to 40m. wide, most of the way about 20m., crosses the southern part of the State from Grand Tower, in Jackson county, on the Mississippi, to Shawneetown, in Gallatin county, on the Ohio, the highest point being 1,065ft. above the sea; from Grand Tower northward along the Mississippi to the mouth of the Illinois there is a slight elevation, and there is another elevation of minor importance along the Wabash. Many of the river bluffs rise to an unusual height, Starved Rock, near Ottawa, in La Salle county, being 150ft. above the bed of the Illinois river. The country south of the elevation (mentioned above) between Grand Tower and Shawneetown was originally covered with forests.

The drainage of Illinois is far better than its low elevation and comparatively level surface would suggest. There are nearly 500 streams in the State, grouped in two river systems, one having the Mississippi, which receives three-fourths of the waters of Illinois, as outlet, the other being tributary to the Wabash or the Ohio river. The most important river is the Illinois which is formed by the junction of the Des Plaines and the Kankakee in the

north-western part of Grundy county. It has a course of nearly 500m., crossing the north-central and western portions of the State, draining 24,726 square miles. At some points, notably at Lake Peoria, it broadens into wide expanses resembling lakes. The Kaskaskia, in the south, notable for its variations in volume, and the Rock, in the north, are the other important rivers emptying into the Mississippi; the Embarrass and Little Wabash, the Saline and Cache in the east, are the important tributaries of the Wabash and Ohio rivers. The Chicago river naturally flowed into Lake Michigan, but by the construction of the drainage canal it was turned in 1900 so that it flows into the Mississippi.

The soil of Illinois is remarkable for its fertility. The surface soils are largely composed of drift deposits, varying from 2 to 100ft. in depth; they are often overlaid with a dark coloured loam 10in. or more deep, and in a large portion of the State there is a subsoil of mottled clay. The soil of the prairies is darker and more granular than that of the forests, but all differences disappear with cultivation. The soil of the river valleys is alluvial and especially fertile, the "American Bottom," extending along the Mississippi from Alton to Chester, having been in cultivation for more than 200 years. Along the river bluffs there is a deposit of loess, well suited to the cultivation of fruits and vegetables.

Drainage has proved an important feature in the agricultural development of Illinois. Of the State's 237,180 farms in 1920, 99,248, or 41.8% were reported as provided with drainage, and 33,731 were reported as in need of drainage. The greatest portion of the land in drainage enterprises was in the eastern and the northern parts of the State, though there were many projects in the central and south-eastern parts and along the Mississippi. The organized drainage undertakings within the State in 1920 controlled 4,820m. of ditch and 3,634m. of tile drains.

Climate.—The climate of Illinois is notable for its extremes of temperature. The warm winds which sweep up the Mississippi valley from the Gulf of Mexico are responsible for the extremes of heat, and the arctic winds of the north, which find no moun-

PROPORTION OF ALL LAND IN FARMS 1925

tain range to break their strength, cause the extremes of cold. The mean annual temperature of Winnebago, near the northern border, is 47°F, and it increases to the southward at the rate of about 2° for every degree of latitude, being 52°F at Springfield, and 58°F in Cairo, at the southern extremity. The lowest temperature ever recorded in the State was 32°F in Feb. 1905, at Ash-ton in the north-west and the highest was 115°F in July 1901, at Centralia, in the south, making a maximum range of 147 degrees. The range of extreme is somewhat greater in the north than in the south. The mean annual precipitation is about 43in. in the

southern counties, but this decreases to the northward, being about 36in. in the central counties and 34in. along the northern border. The mean annual snowfall increases from 17.5in. at the southern extremity to more than 32in. in the northern counties. In the north the precipitation is 44.8% greater in spring and summer than it is in autumn and winter, but in the south only 36.17% greater. At Cairo the prevailing winds are southerly during all months except February, and as far north as Springfield they are southerly from April to January; but throughout the northern half of the State, except along the shore of Lake Michigan, where they vary from north-east to south-west, the winds are mostly from the west or north-west from October to March and are variable for the remainder of the year. Tornadoes are not unknown to Illinois, one of the most severe on record having visited southern Illinois on March 18, 1925. The property loss was estimated at \$16,500,000 and 742 persons were killed and 2,756 were injured.

Government.—Illinois has been governed under two territorial acts of Congress and three Constitutions, the Territorial Constitution Acts of 1809 and 1812, and the three State Constitutions of 1818, 1848 and 1870 (subsequently amended). A new Constitution, submitted to the people on Dec. 12, 1922, was defeated by a vote of 921,398 to 185,298. Amendments may be made by a Constitutional Convention or a two-thirds vote of all members elected by each house of the legislature, ratification by the people being required in either instance. A Constitutional Convention may be called by the general assembly when two-thirds of the members of each house concur and their action, when submitted to the people, is approved by a majority of the votes cast.

The Constitution provides for an executive department consisting of a governor, lieutenant-governor, secretary of State, auditor of public accounts, treasurer, attorney-general and superintendent of public instruction, all elected for four years, with the exception of the treasurer, whose term of service is two years. Despite the difficulty of modifying long-established laws, far-reaching changes have been made. By the Consolidation Act of 1917, over 100 State boards, bureaux and offices, paid and unpaid, created to execute various acts or to supervise the various State debt institutions, were consolidated into nine departments—finance, agriculture, labour, mines and minerals, public works and buildings, public welfare, trade and commerce, registration and education and public health. Reorganization of governmental machinery was begun in 1909 with the abolition of separate boards for the various State charitable institutions and the establishment of one central board of control possessing also certain powers over private charitable institutions. In addition to this board a supervisory State charities commission was created. In 1925, the legislature created a department of purchases and construction and a department of conservation. The heads of these various departments, who are appointed by the governor and senate, have acted as a cabinet for the governor.

Changes in the State's system of appointments were effected by the Act of 1911, which extended the civil service system to the greater part of the State's employees. Civil service now covers all State appointees except those appointed by the governor and confirmed by the senate, the scientific and academic staff of the University of Illinois and the normal schools, and a few others. All examinations are competitive, although for some scientific posts "unassembled examinations" are given which consist of questions as to training and experience. By an amendment of 1917 all appointees may be removed by the appointing authority, but are allowed an appeal to the State civil service commission on allegation that the removal is due to race, politics or religion.

Members of the legislature are chosen by districts, three representatives and one senator from each of the 51 districts, 18 of which are in Cook county. Regular sessions of the legislature meet on the first Wednesday after the first Monday in January in odd-numbered years. The term of senators is four years, that of representatives two years; and in the election of representatives since 1870 there has been a provision for "minority" representation, under which by cumulative voting each voter may cast as many votes for one candidate as there are representatives to be

chosen, or he may distribute his votes (giving three votes to one candidate, or one and one-half votes each to two candidates, or one vote each to three candidates), the candidate or candidates receiving the highest number of votes being elected. A similar system of cumulative voting for aldermen may be provided for by ordinance of councils in cities organized under the general State law of 1872. Special legislation is prohibited when general laws are applicable, and special and local legislation is forbidden in any of 23 enumerated cases, among which are divorce, changing of an individual's name or the name of a place, and the grant to a corporation of the right to the name of a place. The general assembly may pass an act over the governor's veto by a two-thirds vote of all the members elected to each house.

The judicial powers are vested in a supreme court, appellate courts, circuit courts, county courts, justices of the peace, police magistrates, and such courts as may be created by law in and for cities and incorporated towns. The supreme court is composed of seven members elected from districts for a term of nine years. The four appellate courts are distributed one for Cook county (which has also two branch appellate courts, both the court and the branches being presided over by three judges appointed by the supreme court) and three other districts, each with three judges appointed in a like manner. The State outside of Cook county is divided into 17 circuits in each of which three judges are elected for a term of six years. The Constitution provides for separate courts in Cook county. The county has a superior court consisting of 29 judges elected for six years, a circuit court consisting of 20 judges elected for a like term, a criminal court, a county court and a probate court. The City of Chicago has a municipal court composed of 36 judges and a city court consisting of 27 members. Each county has a county court consisting of one judge who serves for four years; in some counties probate courts have been established, and in counties of more than 500,000 population juvenile courts for the trial and care of delinquent children are provided for. Each county has a State attorney elected for a term of four years.

The local government of Illinois includes both county and township systems. The earliest American settlers came from the Southern States and naturally introduced the county system; but the increase of population from the New England and Middle States led to a recognition of township organization in the Constitution of 1848, and this form of government, at first prevalent only in the northern counties, is now found in most of the middle and southern counties. Cook county, although it has a township system, is governed, like those counties in which townships are not found, by a board of commissioners, elected by the townships and the City of Chicago. A general law of 1872 provides for the organization of municipalities, only cities and villages being recognized, though there are still some "towns" which have failed to reorganize under the new law. In 1927 there were 232 cities, 29 towns and 839 villages in the State. City charters are granted only to such municipalities as have a population of at least 1,000. Requirements for suffrage are age of 21 years or more, citizenship in the United States, and residence in the State for one year, in the county 90 days, and in the election precinct 30 days preceding the exercise of suffrage. Disfranchisement is brought about by conviction for bribery, felony or infamous crime, and an attempt to vote after such conviction is a felony.

The relation of the State to corporations and industrial problems has been a subject of important legislation. The Constitution declares that the State's rights of eminent domain shall never be so abridged as to prevent the legislature from taking the property and franchises of incorporated companies and subjecting them to the public necessity in a way similar to the treatment of individuals. In 1903 the legislature authorized the municipal ownership of public service corporations. Railways organized or doing business in the State are required by the Constitution to have a public office where books for public inspection are kept, showing the amount of stock, its owners, and the amount of the road's liabilities and assets. No railway company may now issue stock except for money, labour, or property actually received and applied to purposes for which the corporation was organized.

An anti-trust law of 1893 exempted from the definition of trust combinations those formed by producers of agricultural products and live-stock, but the United States Supreme Court in 1902 declared the statute unconstitutional as class legislation. According to a revised mining law of 1899 (subsequently amended), all mines are required to be in charge of certified mine managers, mine examiners, and hoisting engineers, when the services of the engineers are necessary; and every mine must have an escape-shaft distinct from the hoisting shaft. The employment of children under 14 years of age in factories or mines, as well as working employees under 16 years of age for more than 48 hours a week, is forbidden by statute.

Population.—The population of Illinois at certain selected census periods was as follows:—12,282 in 1810; 157,445 in 1830; 1,711,951 in 1860; 3,077,871 in 1880; 4,821,550 in 1900; 5,638,591 in 1910; and 6,485,280 in 1920. The rate of increase 1910–20 was 15% as compared with 14.9% for the whole United States. The population as on July 1, 1927, was estimated to be 7,296,000. In 1870 and 1880 Illinois was fourth among the States of the Union in population, but in 1890 it ranked third, a position it has since maintained. Of the population in 1920, 97.1% was white, and 80.8% was native born. The principal foreign elements were Germans (205,491), Poles (162,405), Russians (117,899), Swedes (105,577), Italians (94,407), and Irish (74,274). The density of population increased from 100.6 per square mile in 1910 to 115.7 per square mile in 1920. The increase of 1910–20 was urban, the rural population continuing to decline. In 1920 the percentage of urban population in towns and cities of 2,500 or over was 67.9% and 41.7% of the total population lived in the City of Chicago. In 1920, 52.5% of the State's population was in cities greater than 25,000. Population in villages of less than 2,500 declined from 12% in 1910 to 10.5% in 1920. Purely rural population fell from 26.4% in 1910 to 21.6% in 1920.

Population of Cities of over 40,000 in 1920

City	Population 1910	Population 1920	Increase %	Estimated 1926
Chicago	2,185,283	2,701,705	23.6	3,048,000
Cicero	14,557	44,995	209.1	65,400
Decatur	31,140	43,818	40.7	55,000
East St. Louis	58,547	66,767	14.0	72,300
Peoria	66,950	76,121	13.7	82,500
Rockford	45,401	65,651	44.6	78,400
Springfield	51,678	59,183	14.5	64,700

Finances.—Expenditure authorized by the legislature for the biennium 1927–29 amounted to \$263,295,763. Of the appropriations for the biennium, \$102,025,000 was for highway construction and maintenance and \$13,854,420 for interest and retirement of highway bonds, making a total of \$115,879,420 for highway purposes. To meet this expenditure, \$60,000,000 was expected from highway bond issues, and the balance from general income, *i.e.*, receipts other than taxes, including automobile licences, which amounted in the preceding biennium to \$26,800,452. Among other more important items of appropriation were: public welfare department including State charitable, penal and reformatory institutions, \$39,655,686; omnibus bill, \$83,397,459; State treasurer, retirement of and interest on bonds, \$24,578,640; public schools, \$16,001,500; University of Illinois, \$10,725,000; State normal schools, five in number, \$3,241,176; agricultural department \$5,077,258; health department \$1,289,284. The system of revenue is based upon the general property tax; the local assessment of all real and personal property is required, with the aim of recording all kinds of property upon the assessment rolls. Among other sources of revenue are an indirect tax on corporations, motor-vehicle licence fees, an inheritance tax, 7%

DISTRIBUTION OF THE POPULATION IN 1920

of the annual gross earnings of the Illinois Central railway, Federal aid, and various miscellaneous fees. The Constitution prohibits the State from lending its credit or making appropriations in aid of any corporation, association or individual, and from constructing internal improvements, and the counties, townships and other political units cannot incur indebtedness in excess of 5% of their assessed property valuation. The legislature may not contract a debt of more than \$250,000 except to suppress treason, war or invasion unless approved by a vote of the people. The State's outstanding bonded indebtedness on Jan. 1, 1928, was \$145,296,000.

All general banking laws must be submitted to the people for ratification. The northern part of Illinois lies in the 7th Federal Reserve district and the southern part in the 8th, with headquarters respectively in Chicago and St. Louis. In 1927 there were 490 national banks in Illinois with aggregate capital stock of \$99,662,000, aggregate surplus of \$72,601,000 and total resources of \$1,839,001,000. Of these banks 35 are located in Chicago, having resources amounting to \$1,201,548,000. Side by side with the national banks is the system of State banks created by the Act of 1887, and operating under the supervision of the auditor of public accounts. In 1927 there were 1,353 State banks with a total capital of \$173,570,500, and aggregate resources of \$2,778,863,449. Of the State banks 188 were in Chicago, having resources amounting to \$1,997,593,629.

Education.—Public education in Illinois had its genesis in the land of the North-west Territory reserved for educational purposes by the ordinance of 1787. The first school law, which provided for State taxation for public schools, was enacted in 1825. Only a few schools were established under this act as the section providing for taxation was soon repealed. Free schools

GRAPH SHOWING GROWTH OF POPULATION IN ILLINOIS FROM 1810 TO 1920

supported by the sale of land reserved for education and by local taxation were established as early as 1834. In 1855 a second school law providing for a State school tax was enacted, and this is the foundation of the existing public school system; the Constitution of 1870 also requires the legislature to provide a thorough and efficient system of public schools.

The public schools of the State are free to all between the ages of six and 21 years, and school attendance is compulsory for all children from seven to 16 years of age. Of the population of school age (6–21) in 1925, 1,343,430, or 69% were enrolled in

the public schools. In addition to the public schools there were, in 1925, 1,036 private schools with 214,728 pupils. The distribution of public school enrolment was 1,115,285, or 83% in the kindergarten and elementary schools and 228,145, or 17% in high schools. The high school enrolment represents an increase of 168% during a period of ten years. The total number of teachers in 1925 was 43,865 in elementary schools and 9,531 in high schools.

BY COURTESY OF THE UNIVERSITY OF ILLINOIS

ARCHITECTURAL RENDERING OF THE PROPOSED RESEARCH AND EDUCATIONAL HOSPITALS OF THE STATE OF ILLINOIS, A BUILDING GROUP TO BE ADMINISTERED CO-OPERATIVELY BY THE ILLINOIS STATE DEPARTMENT OF PUBLIC WELFARE AND THE UNIVERSITY OF ILLINOIS

School revenue is derived chiefly from local taxation. The net expenditure, including new grounds and buildings, in 1924 was \$115,677,000, or a per caput, based on total population, of \$16.82. This is an increase of \$46,319,000 over the \$69,358,000 expended in 1920. The average length of the school term in 1924 was 8.3 months. A notable development in the public educational system was the growth in the number of township high schools, and the number of community high schools following the legislation of 1917. Under the township high-school law some 200 high schools were organized. Acts of 1913 and 1915 directed the payment by local school authorities of tuition for children who wished to attend high school elsewhere when there was none in their district. During one year, 1920, 232 community high schools were organized, and at the close of the year 1927 the number had risen to 287. The total number of four year high schools in 1925 was 673. With the rapid growth in the number of high school graduates (25,606 in 1925) there was a corresponding increase in the enrolment in the universities and colleges of the State.

The State provides for higher education in the University of Illinois at Urbana and five teachers' colleges situated at Normal, Carbondale, Charleston, De Kalb and Macomb. The university was founded in 1867, through the U.S. land grant of 1862, as the Illinois Industrial university, and received its present name in 1885; since 1870 it has been co-educational. The expansion of the university through the acquisition or organization of new colleges and schools began in 1896 when the Chicago College of Pharmacy became the University of Illinois School of Pharmacy. Since that date important changes have been made. The university in 1928 consisted of a college of liberal arts and sciences, a college of commerce and business administration, a college of education, a college of engineering, a college of agriculture, a college of law, the graduate schools, a library school, a school of journalism, and a school of music at Urbana and a college of medicine, a college of dentistry and a school of pharmacy at Chicago. An agricultural experiment station, an engineering experiment station and the bureaux of educational research and of business research are connected with the university. The faculty in 1927-28 numbered 1,360, and the total enrolment of students for that academic year was 14,071. The five teachers' colleges have an annual enrolment in excess of 12,000.

In addition to the State institutions of higher education in 1927 there were 32 other colleges and universities of recognized stand-

ing and one private normal school within the State. The most important of these are the University of Chicago, Northwestern university at Evanston, Illinois Wesleyan university at Bloomington, Knox college at Galesburg, Illinois college at Jacksonville, and Lake Forest college at Lake Forest.

Charities and Corrections.—The department of public welfare is charged with the administration of all charitable and penal institutions in the State. To accomplish this purpose the department has been separated into a number of divisions and in turn each institution is under a manager appointed by and under the direction of the department. In 1925 there were 26 State institutions under the department's supervision. Of these, nine were hospitals for the insane located at Elgin, Kankakee, Jacksonville, Anna, Watertown, Peoria, Chester, Chicago and Alton. There were two institutions for the feeble-minded, the Lincoln State school and colony at Lincoln and a State hospital at Dixon. The State maintained a school for the blind and a school for the deaf at Jacksonville, an industrial home for blind at Chicago, a training school for girls at Geneva and a like institution for boys at St. Charles. Charitable institutions included a home for soldiers and sailors at Quincy, a soldiers' orphans home at Normal, a home for soldiers' widows at Wilmington, a research and educational hospital connected with the college of medicine of the University of Illinois, and an eye and ear infirmary at Chicago. The State's penal institutions were: a State penitentiary and a woman's prison at Joliet, a reformatory at Pontiac, a State farm at Vandalia and the Southern Illinois penitentiary at Menard. The division of child welfare exercises supervision over all orphanages situated within the State. Poor relief is administered by the counties usually through the maintenance of alms-houses. By a law of 1905 all employees in State institutions were put on a civil service basis. The appropriations for the department of public welfare for the biennium 1927-29 was \$39,655,686.

Industry, Trade and Transportation.—While the census of manufactures shows Illinois to be an industrial rather than an agricultural State, there has been no absolute decline in its farming. According to the census of 1920 Illinois was second only to Iowa among the States in agricultural importance. Based on crop values, in 1926, Texas was first, Iowa second, California third and Illinois fourth with farm crops amounting to \$389,957,000. This production is considerably under the enormous crop of 1924 which had a value of \$554,965,000. The land in farms in 1925 was 30,731,947ac., or 85.7% of the total land area. This figure shows a decline from 90.7% of the total area in 1910 and 89.1% in 1920. The total number of farms has shown a corresponding decline, the numbers being 251,872 in 1910, 237,181 in 1920 and 225,601 in 1925. The average size for farms during the above period showed a slight increase; the 129-rac. average for 1910 increased to 136.2ac. in 1925. The value of farm property increased enormously in the decade 1910-20 but declined sharply after the latter date; the total value of all farm property in 1925 being \$4,628,344,531 as compared with \$6,666,767,235 in 1920. Tenantry showed a slight decrease between 1920-25 but the number paying cash showed a marked decrease because of depressed market values for farm products.

Cereals are still the main crop and corn (maize) is the leading product. The largest maize crop on record was that of 1912 when 426,320,000bu. were produced from 10,658,000ac. or an average of 40bu. per acre. The maize crop of greatest value was that of 1917, which had a value of \$459,800,000. In 1926 the crop of 312,979,000bu. was exceeded by that of Iowa only. In 1926, 41,034,000bu. of wheat were produced on 2,283,000ac., a production which gave Illinois the rank of fifth among the States. The production of oats in 1926 showed a sharp decrease from the average for the 20 years previous; the product being 123,516,000bu., a total exceeded by Iowa and Minnesota only. Rye, barley and sweet corn for canning, are other important cereals. Hay in 1926, had a commercial value second only to that of maize, the production for that year being 3,665,000 tons valued at \$58,640,000. Apples, peaches, cherries, plums and other fruits are widely grown but are little produced for market. The large urban population of the State makes the animal products very

valuable. In 1924 milk and other dairy products had a value of \$62,828,092. In the same year 113,020,993 doz. eggs and 32,203,811 chickens were produced with an aggregate value of \$60,645,711. In live-stock, Illinois, on Jan. 1, 1926, with 1,039,000 milch cows, ranked fifth among the States; and in all cattle, numbering 2,368,000, ranked seventh. In the number of swine, 4,631,000 and the number of horses, 985,000, Illinois ranked second only to Iowa. Mules, 169,000, and sheep 689,000, were of minor importance as compared with other States. The estimated total value of all live-stock within the State on Jan. 1, 1926, was \$289,950,000.

The growth of manufacturing in Illinois, due largely to the development of her exceptional transportation facilities, was the most rapid and remarkable in the industrial history of the United States. In 1850 the State ranked fifteenth, in 1870 sixth, and in 1880 fourth, the same relative position it held in 1923. In 1905 the product of the manufactures was valued at \$1,410,342,129, in 1919 the value was \$3,366,452,969, and in 1923 the total value had risen to \$5,041,113,314. The manufactures in 1923, employed 645,627 wage-earners, working in 14,345 establishments. The most important industry was wholesale slaughtering and the packing of meats, which yielded 12.27% of the total manufactured product of the State in 1923. Illinois has long held first rank in this industry; the product for 1923 exceeded more than twice that of any other State. The manufacture of iron and steel products, and of products depending upon iron and steel as raw material, is second in importance. The iron for these industries is secured from the Lake Superior region, the coal and limestone from mines within the State. The position of Illinois in the heart of the agricultural section and her bountiful supply of iron has caused the State to become the chief producer of agricultural implements. The ten most important industries with the values of their respective products in 1923 were as follows:—slaughtering and meat packing (wholesale) \$606,320,553; foundry and machine shops, \$275,955,047; iron and steel, steel works and rolling mills, \$213,671,552; electrical machinery and supplies, \$211,366,206; clothing, men's, \$186,683,333; cars, steam road (not built in repair shop), \$159,364,227; printing and publishing, book and job, \$138,227,215; printing, publishing, newspaper, etc., \$132,288,355; cars and general construction, steam, \$118,604,362; bread and other bakery products, \$105,289,516.

The tendency in manufacturing was toward large-scale production and corporate ownership. Of the 18,593 establishments in the State in 1919, the 799 producing \$1,000,000 or over, turned out some 75% of the products. In these industries 389,686 wage-earners were employed. Chicago, with its tributary manufacturing suburbs of Maywood, Harvey, Cicero, Blue Island, Chicago Heights, and, in Indiana, Hammond and Gary, is the greatest manufacturing centre of the State. A lesser manufacturing centre has grown up in the net of railways that centre at East St. Louis, Collinsville, Granite City and Edwardsville. The third centre is formed by Moline and Rock Island with Davenport, Iowa. Joliet and East St. Louis were second and third respectively to Chicago in the value of products in 1919. Manufactures in Chicago are generally diversified. The same is usually true in the smaller centres, although a few cities are noted for their special products. Thus, Rockford is best known for its furniture manufactures, Kewanee for boilers, Elgin for watches, Moline for farm implements and automobiles.

In mining and allied interests Illinois occupies an important place. In 1919 the State ranked third in the total number of persons engaged in the mining industries and fourth among the States in the value of products. In the total value of products for 1925 (\$231,658,604), the State ranked seventh, the relative decline in importance being due chiefly to increased petroleum production in other States. Coal constitutes the State's chief product. The great central coal-field of North America extends into Illinois from Indiana as far north as a line from Grundy county to Rock Island, west from Rock Island to Henderson county, then southwest to the southern part of Jackson county, where it runs south into Kentucky, including 54 counties and approximately 35,000 sq.m. of the land surface of the State. During 1926, 69,813,255

short tons were mined with a value equal to 57% of the State's total mineral product. This amount was exceeded only by Pennsylvania and by West Virginia. Clay products were second in importance with an output valued at \$33,591,368. Petroleum, the mineral third in importance, was long known to exist within the State but was not seriously exploited until 1906 when the annual production (4,397,050 bbl.) for the first time exceeded 1,000,000

COAL PRODUCED EACH YEAR 1871-1927

barrels. In 1924 the production was 8,081,000 bbl. valued at \$14,220,000, an output somewhat under that of previous years. The producing area covers about 4,500 sq.m. in 16 counties in the south-eastern part of the State. Limestone, sandstone, sand, fluor-spar, lead and zinc were other leading products. The quarrying industries were well distributed throughout the State and furnished not only stone for construction work, but also limestone for the iron industry, and sandstone from which a large part of the U.S. silica supply is derived. Illinois has ranked as the leading State in the Union since 1842 in the production of fluor-spar, the product in 1924 being 62,067 short tons valued at \$1,288,310.

Transportation facilities have been an important factor in the economic development of Illinois. The first settlers used the waterways, some coming by way of the Great Lakes while others used the Ohio river. The first improved transportation facilities were the turnpikes and canals, undertaken in whole or part by the State. The task of connecting Lake Michigan and the Mississippi river was accomplished by the State's building the Illinois and Michigan canal to La Salle, at the head of the navigation on the Illinois river, a work begun in 1836 and completed in 1848. In 1890 the sanitary district of Chicago undertook the construction of a canal between Chicago and Lockport, where the new canal joins the Illinois and Michigan canal. This work was opened in 1900, providing a waterway with a depth of 20 ft. for navigation between the above places; but from Lockport to Utica, on the Illinois river, a distance of 62 m. there was no adequate means of water transportation. A legislative Act of 1919 provided for the issue of bonds to the amount of \$20,000,000 for the construction of an 8 ft. channel, "The Illinois Waterway," connecting the points mentioned, but little actual progress had been made up to 1925. The Federal Government completed in Oct. 1907 the construction of a new canal, the Illinois and Mississippi, from Hennepin to Rock river. It had a channel 7 ft. deep, 52 ft. wide at the bottom and 8 ft. wide at the water-line. These waterways are not extensively used to-day. Illinois's most important water transportation system is that of the Great Lakes. Receipts of grain at Chicago by lake have steadily declined of late years, although the lakes are still the usual route for shipment of wheat to eastern points. Iron ore is still shipped to Chicago and South Chicago by way of the Great Lakes.

Steam railways are by far the State's chief means of transportation. With 12,037 m. of main line she was in 1924 second only to Texas. For over 30 years little new main line road has been built. The important extension has been in double-tracking and

improvement of the right-of-way and terminals. The field of passenger and light freight and coal transport, since 1900, has been invaded by the electric lines, which in 1924 operated 3,555m. of track. The Illinois traction system operates a ramification of electric lines across the State from Danville to East St. Louis and radiating throughout central Illinois; on certain runs it uses sleeping and parlor cars.

The improvement of roads in the State of Illinois has been given marked attention. A State highway commission was created in 1905, and in 1914 State appropriations for hard roads were made from the proceeds of automobile licence fees. Actual construction was begun in 1914. Road building in Illinois is carried on under four distinct systems—the township, the State aid, the State bond issue and the Federal aid systems. There is an overlapping of mileage among these. Acts of Congress in 1916 and 1919, apportioning Federal aid in behalf of roads, allotted to Illinois \$3,300,000 and \$8,700,000 respectively. The question of issuing \$60,000,000 in bonds based on automobile licence fees for the construction of 4,800m. of hard roads was submitted to the voters of the State in Nov. 1918 and was approved by them. A bond issue of \$100,000,000 providing for the continuance of a State-wide system of hard-surface roads was approved by the people at the general election of 1924. The mileage under the \$60,000,000 bond issue system, according to the last report at the end of 1926, was 4,794 miles. The mileage under the \$100,000,000 bond issue of 1924 is estimated at approximately 5,000m. so that the two systems will provide approximately 9,800 miles. The total net paved mileage in the State under all four systems of construction, excluding city streets, on Jan. 1, 1927, was approximately 5,900m. of which 5,466m. were concrete.

History.—The first Europeans to visit the region now known as Illinois were the French. In 1659 Pierre Radisson and Medard Chouart des Groseilliers seem to have reached the upper Mississippi. It is certain that in 1673 part of the region known as the Illinois country was explored to some extent by two Frenchmen, Louis Joliet and Jacques Marquette, a Jesuit father. Marquette, under orders to begin a mission to the Indians, and Joliet, who acted under orders of Jean Talon, intendant of Canada, ascended the Fox river, crossed the portage between it and the Wisconsin river, and followed that stream to the Mississippi, which they descended to a point below the mouth of the Arkansas. On their return journey they ascended the Illinois river as far as Lake Peoria; they then crossed the portage to Lake Michigan, and in 1675 Marquette founded a mission at the Indian town of Kaskaskia, near the present Utica, Illinois. In 1679 the explorer La Salle, desiring to find the mouth of the Mississippi, ascended the St. Joseph river, crossed the portage separating it from the Kankakee, which he descended to the Illinois, and built in the neighbourhood of Lake Peoria a fort which he called Ft. Crèvecoeur. The vicissitudes of the expedition, and opposition in Canada to his plans prevented him from reaching the mouth of the Illinois until Feb. 6, 1682. After such preliminary explorations, the French made permanent settlements, which had their origin in the missions of the Jesuits and the bartering posts of the French traders. Chief of these were Kaskaskia, established near the mouth of the Kaskaskia river, about 1720; Cahokia, a little below the mouth of the Missouri river, founded at about the same time; and Ft. Chartres, on the Mississippi between Cahokia and Kaskaskia, founded in 1720 to be a link in a chain of fortifications intended to extend from the St. Lawrence to the Gulf of Mexico. A monument of the labours of the missionaries is a manuscript dictionary (c. 1720) of the language of the Illinois, with catechism and prayers, probably the work of Father Le Boulanger.

In 1712 the Illinois river was made the northern boundary of the French province of Louisiana, which was granted to Antoine Crozat (1655–1738), and in 1721 the seventh civil and military district of that province was named Illinois, which included more than one half of the present State, the country between the Arkansas river and the line 43° N. lat., as well as the country between the Rocky mountains and the Mississippi; but in 1723 the region around the Wabash river was formed into a separate district. The trade of the Illinois country was now diverted to the settle-

ments in the lower Mississippi river, but the French, although they were successful in gaining the confidence and friendship of the Indians, failed to develop the resources of the country. By the Treaty of Paris, 1763, France ceded to Great Britain her claims to the country between the Ohio and Mississippi rivers, but on account of the resistance of Pontiac, a chief of the Ottawas, who drew into conspiracy most of the tribes between the Ottawa river and the lower Mississippi, the English were not able to take possession of the country until 1765, when the French flag was finally lowered at Ft. Chartres.

The policy of the British Government was not favourable to the economic development of the newly acquired country, since it was feared that its prosperity might react against the trade and industry of Great Britain. But in 1769 and the succeeding years of English control, this policy was relaxed, and immigration from the seaboard colonies, especially from Virginia, began. In 1771 the people of the Illinois country, through a meeting at Kaskaskia, demanded a form of self-government similar to that of Connecticut. The petition was rejected by Gen. Thomas Gage; and Thomas Legge, earl of Dartmouth (1731–1801), secretary of State for plantations and president of the Board of Trade, drew up a plan of government for Illinois in which all officials were appointed by the Crown. This, however, was never operative, for in 1774, by the famous Quebec Act, the Illinois country was annexed to the Province of Quebec, and at the same time the jurisdiction of the French civil law was recognized. These facts explain the considerable sympathy in Illinois for the colonial cause in the War of Independence. Most of the inhabitants, however, were French, and these were loyalists. The English authorities instigated the Indians to make attacks upon the frontiers of the American colonies, and this led to one of the most important events in the history of the Illinois country, the capture of the British posts of Cahokia and Kaskaskia in 1778, and in the following year of Vincennes, Ind., by George Rogers Clark (*q.v.*), who acted under orders of Patrick Henry, governor of Virginia. These conquests had much to do with the securing by the United States of the country west of the Alleghanies and north of the Ohio in the Treaty of Paris, 1783.

The Virginia house of delegates, in 1778, extended the civil jurisdiction of Virginia to the north-west, and appointed Capt. John Todd (1750–82), of Kentucky, governor of the entire territory north of the Ohio, organized as "The County of Illinois." This government was confined to the old French settlements and was entirely inefficient. In 1787, Virginia and the other States having relinquished their claims to the country west of the Alleghanies, the North-west Territory was organized by Congress by the famous ordinance of 1787. Two years later St. Clair county was formed out of the south-west part of the Illinois country, while the eastern portion and the settlements around Vincennes, Ind., were united into the county of Knox, and in 1795 the southern part of St. Clair county was organized into Randolph county, with Kaskaskia as the seat of administration. In 1800 the Illinois country was included in the Territory of Indiana, and in 1809 the western part of Indiana from Vincennes north to Canada was organized as the Territory of Illinois; it included, besides the present State, all of Wisconsin except the northern part of the Green bay peninsula, a large part of Michigan, and all of Minnesota east of the Mississippi. In 1812, by permission of Congress, a representative assembly was chosen, a territorial constitution was adopted, and the territorial delegate in Congress was elected directly by the people.

In 1818 Illinois became a State of the American Union, the enabling act fixing the line 42° 30' as the northern boundary, instead of that provided by the ordinance of 1787, which passed through the south bend of Lake Michigan. The reason given for this change was that if the Mississippi and Ohio rivers were the only outlets of Illinois trade, the interests of the State would become identified with those of the Southern States; but if an outlet by Lake Michigan were provided, closer relations would be established with the Northern and Middle States, and so "additional security for the perpetuity of the Union" would be afforded.

Throughout the territorial period there was conflict between

French and English land claims. In 1804 Congress established land offices at Kaskaskia and Vincennes to examine existing claims and to eliminate conflict with future grants; in 1812 new offices were established at Shawneetown and Edwardsville for the sale of public lands; and in 1816 more than 500,000 ac. were sold. In 1818, however, many citizens were in debt for their lands, and "squatters" invaded the rights of settlers. Congress therefore reduced the price of land from \$2 to \$1.25 per acre and adopted the policy of pre-emption, preference being given to the claims of existing settlers. The Indians, however, resisted measures looking toward the extinguishment of their claims to the country. Their dissatisfaction with the treaties signed in 1795 and 1804 caused them to espouse the British cause in the war of 1812, and in 1812 they overpowered a body of soldiers and settlers who had abandoned Ft. Dearborn (*see* CHICAGO). For a number of years after the end of the conflict, the Indians were comparatively peaceful; but in 1831 the delay of the Sacs and Foxes in withdrawing from the lands in northern Illinois caused Governor John Reynolds (1788-1865) to call out the militia. The following year Black Hawk, a Sac leader, opened an unsuccessful war in northern Illinois and Wisconsin (the Black Hawk War); and by 1833 all Indians in Illinois had been removed from the State.

The financial and industrial policy of the State was unfortunate. Money being scarce, the legislature in 1819 chartered a State bank which was authorized to do business on the credit of the State. This bank never operated and a second was chartered in 1820. In a few years the bank failed, and the State in 1831 borrowed money to redeem the depreciated notes issued by the bank. A second State bank was chartered in 1835; two years later it suspended payment, and in 1843 the legislature provided for its liquidation. The State also undertook to establish a system of internal improvements, granting a loan for the construction of the Illinois and Michigan canal in 1836, and in 1837 appropriating \$10,000,000 for the building of railroads and other improvements. The experiment proved unsuccessful; the State's credit declined and a heavy debt was incurred, and in 1840 the policy of aiding public improvements was abandoned. Through the efforts of Governor Thomas Ford (1800-50) a movement to repudiate the State was defeated, and a plan was adopted by which the entire debt could be reduced without excessive taxation, and by 1880 practically the entire debt was extinguished.

A notable incident in the history of the State was the immigration of the Mormons from Missouri, about 1840. Their principal settlements were in Hancock county. They succeeded in securing favours from the legislature, and their city of Nauvoo had courts and a military organization that was independent of State control. Political intrigue and claims of independence from the State, as well as charges of polygamy and lawless conduct, aroused such intense opposition to the sect that in 1844 a civil war broke out in Hancock county which resulted in the murder of Joseph Smith and the removal of the Mormons from Illinois in 1846.

The slavery question, however, was the problem of lasting political importance. Slaves had been brought into the Illinois country by the French, and Governor Arthur St. Clair (1734-1818) interpreted the article of the ordinance of 1787, which forbade slavery in the North-west Territory, as a prohibition of the introduction of slaves into the territory, not an interference with existing conditions. The idea arose that negroes could be held as indentured servants, and such servitude was recognized in the Indiana code of 1803, the Illinois Constitution of 1818, and statutes of 1819; indeed, there would probably have been a recognition of slavery in the Constitution of 1818 had it not been feared that such recognition would have prevented the admission of the State to the Union. In 1823 the legislature referred to the people a resolution for a Constitutional Convention to amend the Constitution. The aim, not expressed, was the legalization of slavery. Although a majority of the public men of the State, indeed probably a majority of the entire population, was either born in the Southern States or descended from Southern people, the resolution of the legislature was rejected, the leader of the opposition being Governor Edward Coles (1786-1868), a Virginia slave-

holder, who had freed his slaves on coming to Illinois. The opposition to slavery, however, was at first economic, not philanthropic. In 1837 there was only one abolition society in the State, but chiefly through the agitation of Elijah P. Lovejoy (*see* ALTON), the abolition sentiment grew. In 1842 the moral issue had become political, and the Liberty Party was organized, which in 1848 united with the Free Soil Party; but as the Whig Party approved the policy of non-extension of slavery, these parties did not succeed so well united as under separate existence. In 1854, however, the Liberty and Free Soil Parties, the Democrats opposed to the Kansas-Nebraska bill, and some Whigs united, secured a majority in the legislature, and elected Lyman Trumbull U.S. senator. Two years later these elements formally organized as the Republican Party and elected their candidates for State offices. This was the first time that the Democratic Party had been defeated, its organization having been in control since the admission of Illinois to the Union. An important influence in this political revolution was a change in the character of the population. Until 1848 the Southern element predominated in the population, but after that year the immigration from the Northern States was greater than that from the South, and the foreign element also increased. The influence of immigration and sectionalism upon Illinois politics is well illustrated by the fact that the first six governors (1818-38) were born in the Southern States, six of the eight U.S. senators of that period were also Southern born, and all of the representatives, with one exception, also came to Illinois from the Southern States. After 1838 the Eastern States began to be represented among the governors, but until 1901 no governor was elected who was a native of Illinois. *See* E. B. Greene, *Sectional Forces in the History of Illinois* (Publications of the Historical Library of Illinois, no. 8, 1903).

The opposition to slavery continued to be political and economic rather than philanthropic. The Constitution of 1848, which abolished slavery, also forbade the immigration of slaves into the State. In 1858 occurred the famous contest for the office of U.S. senator between Stephen A. Douglas (Democrat) and Abraham Lincoln (Republican). Douglas was elected, but the vote showed that Illinois was becoming more Northern in sympathy, and two years later Lincoln, then candidate for the presidency, carried the State. The policy of Illinois in the early period of secession was one of marked loyalty to the Union; even in the southern part of the State the majority of the people had no sympathy with the

BY COURTESY OF THE SPRINGFIELD CHAMBER OF COMMERCE

THE LINCOLN HOME AT SPRINGFIELD

pro-slavery men in their efforts to dissolve the Union. The legislature of 1861 provided for a war fund of \$2,000,000; and Capt. James H. Stokes (1814-90) of Chicago transferred a large amount of munitions of war from St. Louis, where the secession sentiment was strong, to Alton. The State contributed 255,092 men to the Federal armies. From 1862-64, however, there was some opposition to a continuance of the war. This was at first political; the legislature of 1862 was Democratic, and for political purposes that body adopted resolutions against further conflict, and recommended an armistice, and a national convention to conclude peace.

The same year a convention met to revise the Constitution. Among its acts was the assumption of the right of ratifying a proposed amendment to the Constitution of the United States which prohibited Congress from interfering with slavery within a State, although the right of ratification belonged to the legislature. The convention also inserted clauses preventing negroes and mulattoes from immigrating into the State and from voting and holding

BY COURTESY OF THE SPRINGFIELD CHAMBER OF COMMERCE

THE OLD STATE CAPITOL AT SPRINGFIELD, USED AS A COUNTY COURT-HOUSE SINCE THE COMPLETION OF THE NEW CAPITOL IN 1887

office; and although the Constitution as a whole was rejected by the people, these clauses were ratified. In 1863 more pronounced opposition to the policy of the National Government developed. A mass meeting, which met at Springfield in July, at the instance of the Democratic Party, adopted resolutions that condemned the suspension of the writ of habeas corpus, endorsed the doctrine of State sovereignty, demanded a national assembly to determine terms of peace, and asked President Lincoln to withdraw the proclamation that emancipated the slaves, and so to permit the people of Illinois to fight only for "Union, the Constitution and the enforcement of the laws." The Knights of the Golden Circle (*q.v.*), and other secret societies, whose aims were the promulgation of State sovereignty and the extension of aid to the Confederate States, began to flourish, and it is said that in 1864 there were 50,000 members of the Sons of Liberty in the State. Capt. T. Henry Hines, of the Confederate army, was appointed by Jefferson Davis to co-operate with these societies. For a time his headquarters were in Chicago, and an elaborate attempt to liberate Confederate prisoners in Chicago (known as the Camp Douglas conspiracy) was thwarted by a discovery of the plans. In the elections of 1864 the Republicans and Union Democrats united, and after an exciting campaign they were successful. The new legislature was the first among the legislatures of the States to ratify (Feb. 1, 1865) the 13th amendment.

From the close of the Civil War until the end of the 19th century the Republican Party was generally dominant, but the trend of political development was not without interest. In 1872 many prominent men of the State joined the Liberal Republican Party, among them Governor John M. Palmer, Senator Lyman Trumbull and Gustavus Koerner (1809-96), one of the most prominent representatives of the German element in Illinois. Economic depression gave the Granger movement considerable popularity, and an outgrowth of the Granger organization was the Independent Reform Party of 1874, which advocated retrenchment of expenses, the State regulation of railways and a tariff for revenue only. A Democratic Liberal Party was organized in the same year, one of its leaders being Governor Palmer; consequently, no party had a majority in the legislature elected in 1874. In 1876 the Greenback Party, the successor in Illinois of the Independent Reform Party, secured a strong following; although its candidate for governor was endorsed by the Democrats, the Republicans regained control of the State Administration.

In 1912, as a result of the Progressive secession, the Republican Party for the first time in 16 years lost control of the State, the

Democratic presidential electors winning by a vote of 405,038, as against 386,478 for the Progressives and 253,593 for the Republicans. The Democratic State ticket headed by Edward F. Dunne was elected by a somewhat larger plurality. The Democrats, however, did not control the general assembly on joint ballot. By 1914 the normal Republican majority in the State reasserted itself, the popular vote for senator in that year being L. Y. Sherman, Republican, 390,661; Roger Sullivan, Democrat, 373,403; Raymond Robins, Progressive, 203,027. President Woodrow Wilson lost the State in the presidential election of 1916 by 160,000 votes. Frank O. Lowden, Republican, was elected governor over Edward F. Dunne. Len Small succeeded Lowden in 1921 and was re-elected in 1925.

The relations between capital and labour have at times resulted in serious conditions, the number of strikes and lockouts from 1916 to 1926 having been 1,671. The most noted instance of military interference was in 1894, when President Grover Cleveland sent U.S. troops to Chicago to prevent strikers and rioters from interfering with the transmission of the U.S. mails.

BIBLIOGRAPHY.—There is no comprehensive bibliography on the literature relating to Illinois; but Richard Bowker's, *State Publications*, part 2 (1902), the chapters of E. B. Greene's, *The Government of Illinois* (1904), and C. E. Carter's, *Great Britain and the Illinois Country 1763-1774* (1910) contain useful lists of documents, monographs and books.

The most comprehensive history of the State is the *Centennial History of Illinois* (published by the State, 1918-20). Older standard histories are J. Moses, *Illinois Historical and Statistical* (1889) and H. Davidson and B. Stuve, *Complete History of Illinois* (1874). Edward G. Mason's, *Chapters from Illinois History* (1901) is of interest for the French explorations and the colonial period. C. E. Boyd in "The Country of Illinois" (*American Historical Review*, vol. iv.), "Record Book and Papers of John Todd" (*Chicago Historical Society, Collections*, iv.); R. L. Schuyler, *The Transition of Illinois to American Government* (1909); W. H. Smith, *The St. Clair Papers* (1882); Solon J. Buck, *Illinois in 1818* (1917) and the *Territorial Records of Illinois* ("Publications of the State Historical Library," no. 3) are important for the period until 1818. Works on special subjects are C. H. Garnett, *State Banks of Issue in Illinois* (1898); N. G. Harris, *History of Negro Servitude in Illinois* (1904); W. W. Lusk, *Politics and Politicians of Illinois, the Illinois Constitutional Convention* (1862); *The Granger Movement in Illinois, and Illinois Railway Legislation and Commission Control* (Univ. of Ill., Studies). See also the *Illinois Historical Collections* and the *Journal of the Illinois State Historical Society*.

Constitutional and administrative problems are discussed in Elliott Anthony, *Constitutional History of Illinois*; E. B. Greene, *The Government of Illinois* (1904); Walter F. and S. H. Dodd, *Government in Illinois* (1923); John A. Fairlie, "Government Reorganization in Illinois" (*American Political Science Review*, vol. ix., no. 21); *Reports of the Efficiency and Economic Commission* (1914-15); and the publications of the legislative reference bureau. The *Blue Book of the State of Illinois* is the best source of current information about officials and administrative organization.

Information concerning population, economic conditions, etc., may be found in the *Fourteenth Census of the United States, State Compendium; Illinois*. Consult also the reports of the various State departments and officials and the *Bulletins* of the Illinois Geological Survey. (D. K.)

ILLINOIS, THE UNIVERSITY OF, an institution of higher learning situated in Urbana, Ill. It arose out of the passage of the Morrill Land Grant Act in 1862, whereby the National Government gave each State in the Union scrip for 50,000 ac. of public land for each senator and representative in Congress "for the endowment, support and maintenance of at least one college whose leading object shall be, without excluding other scientific and classical studies and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts . . . in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life."

The State of Illinois accepted this gift and in Feb. 1867 granted a charter to the Illinois Industrial university. The institution was put under the control of a board of trustees appointed by the governor, excepting two members *ex-officio*, the governor and the State superintendent of public instruction. In 1887 the board was made elective except for the two *ex-officio* members. The university was situated in Urbana-Champaign county, but has extended across the city line into Champaign city, the two cities

being adjacent. In 1885 the name of the institution was changed to The University of Illinois.

The administrative head of the university was known at first as regent. In 1894 the title was changed to president. The university includes at Urbana-Champaign: colleges of liberal arts and sciences, agriculture, engineering, commerce, education, law; schools of library science, music and journalism, and the graduate school. The colleges of medicine, dentistry and the school of pharmacy are in Chicago. A summer session is held at Urbana-Champaign each year. Other great departments are military, physical welfare and health service.

The university has 74 principal buildings in Urbana and Chicago, besides numerous smaller service buildings and 2,298 ac. of land of which 1,925 ac. are devoted to agriculture. The libraries of the university aggregate about 760,000 volumes. The teaching and administrative staff numbered 1,232 in 1928. The student enrolment for the year 1927-28 was 14,071. Of these, the largest group, about 4,200, were in the college of liberal arts and sciences.

In addition to the instructional work of the university, much research is carried on. The agricultural and engineering experiment stations are devoted to research in their respective fields. In all other departments of the university research is carried on either individually or co-operatively. Notable discoveries have been made in various departments, the most noted, perhaps, being the discovery of the element illinium in the chemical laboratory of the university in 1925, this being the only chemical element discovered in the Western Hemisphere. The work of the experiment stations is far-flung. The engineering station assisted in experiments for the ventilation of the New York and New Jersey vehicular tunnel under the Hudson river, as well as in other projects of a similar character.

The main financial support of the university is from State appropriations. In addition, the university receives certain Federal appropriations and has an income from student fees and from various other sources. For the biennial period 1925-27 the budget income for all purposes aggregated \$15,678,560. Of this amount \$10,529,914 were State appropriations. (D. K.)

ILLINOIS CENTRAL SYSTEM is the principal north-and-south railroad of the United States. It was incorporated in 1851 to build lines between Cairo and East Dubuque and between Centralia and Chicago, in Illinois. Construction was completed in 1856. Additional lines were subsequently built or acquired in Illinois, Indiana, Wisconsin, Minnesota, South Dakota, Nebraska, Iowa, Missouri, Kentucky, Tennessee, Arkansas, Louisiana, Mississippi, Alabama and Georgia. The system, including the owned but separately operated Central of Georgia Railway, consisted in 1928 of 9,183 m. of line. Three-fourths of the railroad's operating revenue is derived from freight traffic, the principal commodities being coal, lumber, petroleum, sand, gravel, stone, cement, grains, livestock, cotton, fruits and vegetables and miscellaneous manufactured products. Through passenger trains are operated between Chicago and St. Louis and Memphis, New Orleans, the Mississippi Gulf Coast, Birmingham, Savannah and the Florida resorts, and between Chicago and Omaha, Sioux City and Sioux Falls. A subsidiary, the Ocean Steamship Company of Savannah, operates a fleet of steamships between Savannah and New York and Boston. The total investment in property on Dec. 31, 1927, was \$828,920,000. (L. A. D.)

ILLITERACY. In the more restricted and technical sense of the term an illiterate person is one who is unable to read and write his own language. The tests of this ability vary greatly, but all are so simple that a person could easily pass them and yet be illiterate in the wider sense.

It has been estimated very roughly that about 60% (820,000,000 persons) of the world's population over 10 years of age cannot read or write. For large parts of Africa, Asia and the Pacific Islands only rough guesses at the population can be made, and illiteracy is considered absolute. In some Catholic countries and in all Mohammedan and Asiatic countries the illiteracy of the female population greatly exceeds that of the male. In some Asiatic countries it is almost complete. The least illiteracy in the

world is to be found in the countries to the west and north of Europe, and in countries settled by them. A reason often given for their low percentage of illiteracy is that the Protestant Reformation emphasized the reading of the Bible and thus gave the first incentive to the education of all classes. Church schools initiated such teaching and for a long time retained control of education.

Unfortunately statistics of illiteracy are not collected in a uniform manner in various countries, nor do given figures represent the same age groups, so that much of their value for comparative purposes is lost. To intelligently reveal conditions illiteracy should also be classified as to sex, nationality and race. Only the first is possible in the table given below. Norway, Sweden, Germany and Switzerland claim a negligible amount of illiteracy. Germany ceased keeping statistics in 1913 when her male percentage as revealed by army recruits was .05. Illiteracy statistics for Great Britain were based upon the proportion of those signing their names in the marriage register with a mark, but even these ceased to be included in the Registrar-general's annual report in 1914 when the percentages stood at 0.8% for males and 1.0% for females. In 1841-45 the figures had been 32.6% and 48.9% respectively. For other important countries the percentages are given in the following table:—

Country	Source	Ages included	Male per-centage	Female per-centage	Year
Australia	Census	Over 5 years	4.6	3.8	1921

United States	Census	Over 10 years	6.0	5.9	1920

*Census (1920) for Russia in Europe showed 49.8% male and 71.8% female illiteracy.

Illiteracy statistics are most complete in the United States. (See UNITED STATES: *Population and Social Conditions*.) The comparatively high percentage of illiteracy there where education is compulsory was due chiefly to the adult negro and foreign-born populations. The illiteracy of native whites in 1920 was 3.0%, of foreign-born whites 13.7%, of children of foreign parents 0.9% and of negroes 27.4%. The low percentage of illiteracy among children of the foreign-born reveals how eagerly the foreign-born take advantage of free education. Negro illiteracy was reduced from 30.4 in 1910 to 22.9% in 1920. The illiteracy among native whites was found chiefly in the isolated rural districts of the older states and in the newer states where the demands of the frontier had prevented an older generation from receiving their educational inheritance. Illiterates among arriving immigrants decreased from 23.5% in 1900-09 to 0.9% in 1926 due to new immigration laws.

Illiteracy in the United States by Geographical Divisions, 1920

	All classes	Native white	Foreign-born	Children of foreign-born	Negroes

ILLORIN, a province of northern Nigeria, British West Africa. Area 17,779 sq.m.; population (1926) 519,627. It lies west of the Niger and is bounded west by French territory (Dahomey). The province consists mainly of open plains and river valleys and is separated from southern Nigeria by a range of well wooded, iron stone hills. The chief division is the emirate of Illorin, occupying the centre. In the north is the Borgu division made up of the emirates of Kaiama and Bussa. In the east are the Pategi and Lafiagi emirates. The predominant native race is the Yoruba (*q.v.*), but in the districts by the Niger the Nupe prevail. The province is rich in agricultural and sylvan products. Among the former are cotton, rice, peppers, ground-nuts and kolos. The latter include great quantities of shea as well as palm-oil and rubber. The Government maintains an experimental farm in the province, where attention is given largely to cotton and ground-nuts as sources of a big export industry. The capital, also called Illorin, is 160 m. in a direct line north-north-east of Lagos, and is on the railway from that port to Kano. The town (pop., 1926, 83,669) is surrounded by a mud wall partly in ruins, which has a circuit of some 10 miles. Illorin is a great trading centre. A variety of manufactures are carried on, including the making of leather goods, carved wooden vessels, finely plaited mats, embroidered work, shoes of yellow and red leather and pottery of various kinds. Before the establishment of British rule Illorin middlemen transacted all business between the traders from the north, who were not allowed to pass to the south, and those from the south. On the establishment of British authority the town was thrown open to all traders and a number of European merchants are established there. The chief buildings are the British residency, the palace of the emir, the houses of the *baloguns* (war chiefs), mosques and churches. From the centre of the town roads radiate like spokes of a wheel to the various gates. Baobabs and other shade trees are numerous.

The town of Illorin was founded, towards the close of the 18th century, by Yoruba, and rose to be the capital of one of the Yoruba kingdoms. About 1825 the kingdom, which had been conquered by the Fula, became an emirate of the Sokoto empire. The Fula, however, maintained the Yoruba system of government, which places the chief power in a council of elders. In 1897 Illorin was occupied by the forces of the Royal Niger Company, and the emir placed himself under the protection and power of the company. After the assumption of direct authority by the British Government in 1900, Illorin was organized for administration on the same system as the remainder of northern Nigeria. The Yoruba showed a keen appreciation of education, to which the Nupe remained indifferent. (See **BORGU** and **NI-GERIA**.) (F. R. C.)

ILLUMINATED MANUSCRIPTS. Illumination, in art, is a term applied to the embellishment of written or printed text or design with colours or gold and, rarely, with silver. The old form of the verb "to illuminate" was "to enlumine," and 13th century laymen who practised the art were called "enlumineurs." While the term should be strictly applied to the brilliant book-ornamentation which was developed in the middle ages, it has been extended, by usage, to the illustration and decoration of early mss. in general.

The decisive changes in the history of the book are similarly

turning points in the art of illumination. (See **BOOK**.) The production of precious illuminated mss. survived the introduction of printing by nearly a century. So far as we know, the art of decorating mss. did not create new forms through a development based on writing, but rather it took over pictures and ornaments from other forms of art. The written pages appear at first simple and unadorned, even where the parchment is coloured and the writing is in silver or gold; then simple enlarged initial letters and calligraphic ornament; in the Codices richly adorned title-pages and brilliant displays of ornament in the Canon-tables of Gospel mss. The form and position of the pictures vary exceedingly. Sometimes the illustrations are placed haphazard in the picture borders, in the text, or as framed pictures in the text; they may also occupy full pages, or in the form of a running band in the Codex above or below the text, or, as in the roll, running in a continuous series of pictures from end to end.

Illumination in Antiquity.—The little surviving from the first great period in the history of illumination which reached to about the 4th century, consists of numerous fragments of papyrus rolls. Such fragments include the ancient *Egyptian Book of the Dead*, in which the illustrations are either dashing drawings or coloured pictures. The only fragmentary examples of illustrated rolls of the classical period were found in Egyptian excavations, and our knowledge of this period, as a whole, is very slight. The most ancient and important of these are the fragmentary copy of the *Iliad*, on vellum, in the Ambrosian library, Milan (variously assigned to the 3rd and 5th centuries), of which there are 58 pictures of various sizes, obviously the remains of a magnificent ms.; the small Virgil at the Vatican (Lat. 3,225, 4th century) with pictures set off in a simple frame and inserted in the text, all of which are considered to have been based on Augustan models; and the later Vatican Virgil (*Codex Romanus*, Lat. 3,867, 5th or 6th century), the work of an artist who did not understand his model's technique in painting and was, therefore, unable to copy it. (See **MANUSCRIPTS**, **PALAEOGRAPHY**.)

Illumination of Christian Books in the East.—Christian illumination dates back to the times to which the few early profane illuminated mss. in our possession belong. The number of ancient Christian illuminated mss. in Greek or in oriental languages is very small. (See **BIBLE**, **MANUSCRIPTS**.)

Other Theological and Profane Manuscripts.—Among illuminated theological or profane mss. which survive in the original, the most important is the *Dioscorides* (early 6th century) in Vienna. Few of the manuscripts are dated and localized and many important to early Christian art are preserved only in mediaeval copies; even those actually written in early Christian times may not be originals, but merely copies. Only on this basis can we explain why the Viennese *Genesis*, made up of various series of illuminations, is closely allied to the *Codex Rossanensis*, which belongs to another stage in the development of the style. The style is determined mainly by paintings of late antiquity based on Hellenistic models influenced by indigenous art (Coptic, Syrian, etc.).

Miniatures in the Middle Byzantine Period.—The development in Byzantium cannot be traced clearly until after the iconoclastic controversy. As art flourished again, the works of the Byzantine Renaissance, as it is called, began to be produced. To this renaissance belong those Codices which hand on works of late antique or early Christian times, partly in accurate copies, partly in free imitations (Joshua Roll, Kosmas Indikopleustes), Psalters like that at Paris (Grec. 139). On the other hand, the typical middle Byzantine art modelled its style on monumental art.

Although Constantinople decided the trend of artistic production, illumination was also cultivated outside the capital. As practised in the monasteries of Athos, its importance was far-reaching. From the 11th century a school of miniaturists developed in Russia, the works of which are, at first, scarcely to be distinguished from those of Byzantium. The *Menology* at the Vatican is the only Byzantine ms. in which each miniature is signed by the artist. The style in the later works, and especially in the productions of the monasteries, became dry, but still it persisted,

not only through the Latin conquest (1204-61), but it was also capable of a rebirth after the restoration of the empire under the Palaeologues (1261).

Western Illumination in Early Christian and Carolingian Times.—Few early Christian illuminated manuscripts of Western origin have survived. A comparison between the Quedlinberg Itala fragment in Berlin of this period and the Virgil of the Vatican (Lat. 3,225) proves that the scriptoria which produced it also executed Christian illuminated mss. The affinity between the two is extraordinarily close; the style is clear and simple in character; the pictorial conception gives evidence of naturalness and it is without a trace of the Byzantine spirit. There is evidence that style quickly deteriorated in the West, but the process cannot be traced in detail.

The most important original ms. is St. Augustine's Gospels at Corpus Christi, Cambridge (Nr. 286) which was probably executed in Lower Italy. The Ashburnham Pentateuch at Paris is of a different type; its 19 miniatures are stylistically and iconographically unique, and indicate a connection with oriental models; they are possibly of Spanish origin. These mss. bear witness to a survival of late antique and early Christian art in the West. By comparison, the mass of the mss. produced in the monasteries of the Frank and Lombard kingdoms in the 7th and 8th centuries have quite a different character. Among the large number preserved only a few have figurative representations. Illuminated Bibles or Gospels hardly occur at all. Ornament, in general, is restricted to initials and decorated pages, a method of embellishment based on the art of the *scribe*, not of the *painter*. Compared with the simplicity of the text in late antique mss., it is a complete revolution. Part of the material originated in upper Italy and south France, apparently in the early 7th century. Later, the art was transplanted to central and northern France. The majority of the mss., and especially those richest in decoration, arose in north France in the latter half of the 8th century, *i.e.*, not until the Irish and Anglo-Saxon arts of illumination were already highly developed.

In Britain two fundamentally different tendencies must be distinguished, the Irish and the English. The development in England was determined by the Roman mission and by the close relations kept up between the Italo-Saxon churches and monasteries and Rome itself. In the 8th century, from which period a series of splendid mss. have been handed down, the artists endeavoured to continue the early Christian figurative tradition in stiffly outlined forms, and at the same time displayed rich decorative splendour in the Irish fashion. The most important works of the Canterbury school are S. Augustine's Psalter with a portrait of David (British Museum) and the Codex Aureus in Stockholm.

Irish Illumination.—In spite of numerous contacts with England, Irish illumination is a world apart. It is one of the most interesting phenomena in the whole range of mediaeval art. In the art of illumination it represents, perhaps, a climax never again reached. It is the more remarkable in that it suddenly appears before us, fully developed, without any preliminary stages and with no source to which it can be traced. The three chief Irish works are the Book of Durrow (Dublin, Trinity college, A. 4, 5.), the Book of Kells (*ibid.* A. 1, 6) and the Lindisfarne Gospels (British Museum Cotton, New D. IV.). The Book of Durrow (*c.* 700) is pure Irish in style; the Book of Kells (for which the date 700 has been disputed in favour of a later period) shows traces of foreign ornamental ideas, and the Lindisfarne Gospels (written soon after 700), have pictures of the Evangelists, which are not Irish in style, but are only explained by the influences of the Italo-Saxon monasteries. The contrast arises from the refusal of the Irish artists to attempt naturalistic representation in order to make as free play with the figures of a picture as if they were calligraphic designs, that it is often difficult to see what these plaited figures really mean. This anti-naturalistic method of representation stands in sharp contrast to the whole range of classical antique art in all its derivations. Irish mss. show a richness of decoration unparalleled, so far as is known, up to that time. The various Gospels are preceded by whole pages with carpet-like designs, and the initials at the beginning of the text grow and spread until they,

too, cover the whole page.

The Carolingian Renaissance.—Simultaneously with the reform of writing, a project of Charlemagne, there arose a number of new schools of painting which aimed at restoring the connection with antique and early Christian art. The chief works probably did not arise before the beginning of the 9th century; they include the Gospel-book of Ada (? Charlemagne's sister), at Trier, after which we call all these works the Ada-group. These mss. include rich Canon-tables, pictures of the Evangelists and of their symbols under large arcades, symbolical representations of the Church, the Fountain of Life, etc. Obviously there is an ancient pictorial tradition, which we can trace back, on the one side to Syria, on the other to Italy and England. The colouring is varied and splendid, the figures dramatic in movement, the faces fine and full of expression, the outlines of the figures rich in style. On the whole, the treatment, with its sharp and clear outlining of form, shows more of the spirit of drawing than of painting. All this points to models of high artistic importance.

Of a group of schools where work is in decided stylistic contrast to the Ada group is the Palatine school of Aix-la-Chapelle. Its chief work, the Gospel-book of Charlemagne, is preserved among the Crown treasures at Vienna. The treatment is altogether pictorial, the colouring fine and simple without being too varied. The plain style of embellishment, with the greatness of conception in the figures and the soft pictorial treatment, point to early Christian models. This tendency is continued in the school of Hautvillers, where a Gospel-book at Epernay town library was made for Ebo of Reims (816-35). Significant changes of style have set in however; the broad pictorial technique has made room for a hatched treatment, so that it has been supposed that the artist had been accustomed to using a drawing-pen. The style is that of the Utrecht Psalter, which has great affinity with later Anglo-Saxon work, and which subsequently exercised a strong influence on development in England. The Utrecht Psalter (Utrecht University library), is at once the most magnificent and the strangest production of Carolingian art. The composition with landscape like stage-scenery reminds one of early Christian models (Joshua-roll). Without a doubt, the Utrecht Psalter has some connection with early Christian art. Nevertheless, it is an essential creation of Carolingian times. The school of Tours was at its prime towards the middle of the 9th century under the lay abbot, Count Vivian. The Gospel-book destined for the emperor Lothaire is the most important work (Paris B.N., Lat. 266). The Tours mss. took over from early Christian models a large number of Bible illustrations, and introduced them into mediaeval art. A quite distinctive style marks the works of the Franco-Saxon school. It shows, unmistakably, a continuation of the Irish and Hiberno-Saxon school, enriched by Carolingian elements. Its strength is based entirely on ornament and it is notable for having spread the art of the initial as developed in England and Ireland.

Anglo-Saxon Illumination.—Anglo-Saxon illumination began to flourish once more under King Edgar (*c.* 960). The new style, based on Carolingian art, suddenly makes its appearance completely developed, in the works of the Winchester school. It is one of the most original and attractive in the whole range of mediaeval art. The artist is not satisfied by normal movements of the neck or head, so the line of the neck is unnaturally prolonged and curved; the draperies appear as if driven by a gale of wind, and end in fluttering points; the seams are broken into numberless small folds. From the standpoint of correctness, much fault might be found with these figures, but as the expression of immense spiritual force they excite our wonder. Anglo-Saxon art, too, reaches its climax when it dispenses with painting in thick colours and contents itself with sketch-like drawings, which may be tinted with various light colours. The chief work of the early period is the Benedictional, which Bishop Aethelwold (963-984) caused to be written, by the scribe Godeman (Chatsworth library).

One of the most important seats of Anglo-Saxon art was at Canterbury. A copy of the Utrecht Psalter (Brit. Mus. Harl. 603) is supposed to have been executed there. More than three hands worked at it, so it must have been made in a large scrip-

BY COURTESY OF THE PIERPONT MORGAN LIBRARY, NEW YORK.

BLANCHE OF CASTILE AND SAINT LOUIS, KING OF FRANCE

Leaf from a *Bible Moralisée*, showing portraits of Blanche of Castile and her son, Saint Louis, king of France. This reproduction is from the original French manuscript, executed in the first quarter of the 13th century, now in the Pierpont Morgan library, New York

torium. The Anglo-Saxon style remained full of life until the middle of the 11th century. It was not confined to England; during the 10th century it crossed the Channel. There the style appears in many works in such freshness and spontaneity that it is likely that Anglo-Saxon artists had emigrated to France. Of this type is the Evangeliar (Boulogne library, No. 11) written at the Abbey of S. Bertin. In northern France there arose, side by side with the illuminations influenced by the Anglo-Saxons, other mss. which, independent in style, are full of intense expression.

The Ottonian Renaissance.—The Ottonian Renaissance flourished in Germany about the same time as the Winchester school. Its political background was the renewal of the Holy Roman Empire by Otto I. Within a few decades an almost inconceivable abundance of magnificent mss. was produced, which we can allot to a number of different schools. These schools differ exceedingly in character, according to whether the artists used Carolingian models or went back direct to early Christian. Middle Byzantine art, too, begins to exercise its influence at this period. The great number of pictures in the Ottonian mss. springs from these various sources. All these schools, on the other hand, are very creative in ornament. They used whole page illuminations with a purple ground and richly formed initials of golden foliated branch work, similar to those found occasionally in Carolingian times, especially in the Metz school. In all the schools of the Ottonian period, painting with thick colours prevails. In the works of the golden age of Ottonian art we notice the intention to approach the illusionistic conception of the late antique. But these endeavours are soon frustrated, and at the beginning of the 11th century decline sets in. The painting becomes more mediaeval in character, the background of the pictures is divided up by ornamental and coloured stripes, for which occasionally the Byzantine gold background is substituted. One of the most prominent centres of artistic activity was the monastery of Reichenau, situated on an island in Lake Constance.

Romanesque Illumination in England, France, Germany and the Low Countries.—Middle 11th century illumination stands at the parting of the ways. Anglo-Saxon schools and the German Ottonian Renaissance were dying out, and so the connection with antique painting disappears. From now onwards the whole of the West is governed by a style based on linear, not pictorially treated, outline-drawing, for which colour is used to tint the surfaces in the flat, with only slight modelling of forms. Art abandons the last reminiscences of the illusionistic manner of the late antique, in which the picture was based on a reality seen either bodily or in the mind's eye. The mediaeval style, which now establishes itself, dispenses with illusion, it gives us the different components of the pictures, *i.e.*, the figures and whatever else is necessary to understand the action, but releases them from contact with natural space. Even the background has chiefly an ornamental importance. A gold ground becomes more and more popular, or border and background consist of a system of frames. This manner of representation permits the artist to pack the most complicated ideas into a picture, if only he has created the corresponding frame to hold the conceptions together, and this tendency now completely dominates the art of illustration. A counter movement is only to be seen in Byzantine art which never altogether lost contact with the antique, and which preserved formulas from the illusionistic age. In the 12th and 13th centuries Byzantine influence penetrated further and further forward into Italy and obtained a strong hold in Germany.

In the West of Europe, especially in northern France and in England, Byzantine influence may also be traced, but it was powerless to check the development which led to Gothic painting, and which was furthered most of all by the art of stained glass. For technical reasons, stained glass, with all its beauty of colour, can never know real modelling; it is based on outline-drawing in the proper sense of the word. It had an extremely strong influence on the method of painting, described above, in which numerous figurative representations are combined within a system of frames. Already, in the 12th, and especially in the 13th century, many illuminated mss. show evident traces of having been imitated from

stained glass.

Anglo-Norman Illustration.—Soon after 1100 we find various Anglo-Norman scriptoria at the height of their power. Their productions are chiefly enormous Bibles, separate books of the Bible with commentaries, and especially the Psalter. The style abandons the lightness of Anglo-Saxon times. It is now based on stiff linear designs filled up with opaque pigments of harsh colour. The figures are, especially early in the 12th century, heavy and awkward. A little later the style becomes more spirited. The initial ornaments are astonishingly rich in invention and design, and they are enlivened with numerous fantastic forms of men and animals in strange colours.

Bury St. Edmunds produced the first of the large Bibles so characteristic of the 12th century. Winchester again became, about the middle of the 12th century, the seat of an important school. It produced the Psalter of Bishop Henry of Blois (British Museum, Nero C. IV.).

The wave of Byzantine art had now reached England also and the deeply agitated style with its singular types is replaced by an almost classical conception of art. The chief work of this tendency is the Winchester Psalter of the British Museum. Well-proportioned forms of measured placidity and solemnity of movement meet us in these pictures. Of the greatest importance is the latest copy of the Utrecht Psalter, which was only finished afterwards in Italy (Paris B.N. Lat. 8846).

Continental Schools.—Our knowledge of the history of miniature in France is altogether much slighter than in England. We know of the quick rise and decline of an important scriptorium at Cîteaux, the founder of which was Abbot Stephen Harding. Numerous mss. with most peculiar decoration, especially initial letters of quite fantastic formation, emanate from Limoges and western France. The productions of monasteries in Belgium and northern France are extraordinarily numerous. Many of these are dated and indicate the names of the artists. In the eastern part of this territory, a style approaching the Rhenish predominates, while towards the west, where the narrowness of the straits provided a natural connection with England, the Anglo-Norman affinities already mentioned make their appearance.

In these districts, also, we can establish the presence of a strong Byzantine influence in the critical period round about 1200.

In Germany the development of art, after the Ottonian Renaissance, varied in the different territories. In the south-east, the Middle Byzantine influence, already perceptible in the early 11th century, now became permanent.

In the western and northern districts of Germany Byzantine influence was not so powerful in the 12th century. One work, however, the famous *Hortus Deliciarum* of the abbess Herrad of Landsberg, in Alsace, occupies a position of its own on account of the unusual illuminations it contained. (The original perished in 1870.) Pure pen-drawing had spread in all directions. On the lower Rhine and in north Germany some miniatures were executed in opaque pigments. These are clear and calm in style, and at times they rise to an extraordinary height of monumental dignity, *e.g.*, in the Gospel Book of unknown origin at Paris (B. N. Lat. 17,325) or the Hildesheim mss. of the 12th century (Hildesheim, Ratman Missal, etc.).

With the beginning of the 13th century Byzantine influence extended its power over almost all the country, and its style displays great restlessness. In the latter part of the 13th century the desire to create original forms and to express passionate feeling was so strong that the style was often positively distorted. The Byzantine tendency attains its zenith in the Gospel-book of the town hall at Goslar, and the Missal (Pierpont Morgan's library), executed in the first third of the 13th century. Immediately after the middle of the 13th century numerous fine works were produced, especially in south Germany, where refined Byzantine style predominated (Psalter, Munich, Staatsbibl. Lat. 3,900).

Gothic Illumination in France, England, Germany and the Lower Countries.—In the first half of the 13th century a complete change came over French illumination which transformed the fundamental ideas of book-ornamentation. It is based, to begin with, on the cultivation of a refined and dainty style which

caused the contrast between miniatures in Gothic mss. and the art of monumental painting to appear sharper than ever before. It rested, moreover, on the closer assimilation of picture and text, so that the historiated initial becomes predominant in Gothic mss. When the miniature remained independent, it bears the character of a small medallion or of a quatrefoil. The initials, however, expand more and more until they have twined themselves all round the pages of text. Figures dispersed at random in the margin, called drolleries, although they may represent any sort of object conceivable, introduced a new style of embellishment on which all development to 1500 is founded. Paris is regarded as the birth-place of the new style. Several mss. are designated as the property of Queen Blanche or of St. Louis, among them the Psalter of the Arsenal library in Paris. It is the first to show the substitution of medallions for the usual rectangular series of pictures. From other books it is still clearer that the illuminators are keeping very close to the example of stained glass windows (see Colour Plate), from which they borrow the complicated arrangement of the medallions.

Great as is the advance made by the mss. of the *Bible moralisée* and the allied mss., they had not yet produced the pure type of Gothic ms. Many other miniatures, however, display a strongly dramatic and restless style, which has a certain affinity to contemporary German work rather than with French Gothic. A number of splendid mss. which are supposed to emanate from Salisbury, are illustrated in this style. Early English examples include the magnificent pictures of the Apocalypse at Trinity college, Cambridge. A great new style, which was to oust all the previous tendencies in France and England, was created under the strong influence of monumental art in Paris about the middle of the 13th century. Its chief works are the Psalters written for St. Louis or other member of the royal family (Paris B.N. Lat. 10,525) and the liturgical mss. executed for the Ste. Chapelle. These works combine two qualities, firstly, the greatest simplicity of style, in that they work out the pure Gothic line, and secondly, a marked attention to reality in ornament and in architectonic details, in costume, etc. It is very difficult to distinguish between French and English work of this period. In spite of numerous English traits we can probably localize in Paris the Psalter of the municipal library at Nuremberg and the Psalter of Queen Isabella, Edward II.'s wife, at Munich. Queen Mary's Psalter at the British Museum is, beyond dispute, an early 14th century English masterpiece. In the work of the East Anglian school can be seen the gradual giving up of Gothic outline-drawing for the sake of a broader pictorial treatment. Its most singular characteristic is extravagant richness of ornamentation displayed in the large border-frames of the decorated pages, interlaced with figures of every shape and kind. In Parisian illumination the characteristic style of the miniaturist, Jean Pucelle, shows the change unmistakably. From now onwards we can follow in the miniatures of the mss. the development of modern painting. The fundamental revolution in style which takes place during this period can only be explained on the assumption of Italian influence arising out of the close connection between Italian and French art, based, in its turn, on political and dynastic relations and the transference of the papal court to Avignon. This may account for the fact that one of Pucelle's masterpieces, the Breviary of Queen Jeanne of Navarre (Yates Thompson collection), contains certain miniatures that can only be understood as imitating Italian pictures of the Trecento.

From the middle of the 14th century onwards, the naturalistic tendency becomes more and more powerful. For this period the phrase, "the naturalism of head and hand," has been coined. Its influence is seen most clearly in the dedication-pictures, where the elements of portraiture in the persons represented, as e.g., Charles V., are unmistakable. In religious pictures, however, Gothic idealism continued until the beginning of the 15th century. The miniatures executed for Charles V. are often set in *quatrefoil* frames, and grey monochrome (*grisaille*) is preferred to painting in colours. The decisive change in the direction of modernity may best be studied in the mss. illuminated for Charles V.'s brother, the duke of Berry. The name of André Beauneveu, of

Valenciennes, is given for the Psalter at Paris (B.N. Fr. 13,091), that of Jacquemart de Hesdin for the Prayer Books at Paris (B.N. Lat. 919) and Brussels (B.R. 11,060-61). In these mss. there is a change in the borders, the dainty sprays of ivy, which had hitherto sprouted loosely over the margins, now completely fill them up, and new *motifs* add to the wealth of ornament. In the miniatures we can see the old Gothic tradition gradually being displaced by Italian art, with a rapid progress in naturalism. The new art reaches its climax in the second decade of the 15th century in two mss. begun for the duke of Berry, which must be classed, beyond dispute, among the most magnificent illustrated books of all times. The unfinished Prayer Book at Chantilly (called, according to the Inventory, *Très riches Heures du duc de Berry*), was illuminated by Pol de Limbourg and his brothers. Pictures which remind us of famous Italian mural paintings stand side by side with faithful representations of reality, as e.g., the Calendar-pictures with the views of the duke's castles or the genre-like February snow-landscape. We are taken a step further by the Prayer Book begun for the duke of Berry, but after his death continued for Count William IV. of Bavaria-Holland. In the pictures of William IV.'s time the Italian style has been completely replaced by a style so near to that of the brothers van Eyck that some of the best pictures have been attributed to them. The miniatures of the two last-named mss. are invaluable to the history of painting.

Spanish and Italian Illumination in the Middle Ages.—

Spanish and Italian illumination had only a slight share in the Renaissance movement on which Carolingian, Ottonian and Anglo-Saxon art was based. In Spain, as in Italy, tendencies prevailed, during this period, which can best be compared with the Franco-Saxon school. The Spanish mss. of the 9th to 11th centuries display a rich, but fantastic decoration in which early Christian and Moorish elements are mixed. The figures are anti-naturalistic, reminding one of the Irish style. The most singular Spanish creation is the great series of illustrations to Beatus of Liebana's Commentaries on the Apocalypse which have survived in many copies from the 9th (?) to the 12th centuries (the oldest in the Yates Thompson college, a later one in the P. Morgan library).

The character of Italian illumination varies extremely in the different Italian territories, according to their relations with East and West. A curious blend of contrasting tendencies is to be seen in the book-ornamentation of the Benedictines at Monte Cassino in the 11th and 12th centuries. Here Hiberno-Saxon, Ottonian and Byzantine stylistic elements are intimately combined. Southern Italy made a speciality of Exultet-rolls, as they are called, i.e., mss. adorned with miniatures and written in the form of rolls. Various Italian monasteries produced, from the 11th to the 13th centuries, gigantic Bibles, some of which show a singular beauty of initial which was afterwards imitated in the 15th century. The origin of these Bibles is partly to be sought in Tuscany, where, in the reign of the margravine Matilda, works of a pronounced original character were produced, e.g., the Gospel-book which Matilda presented, in 1109, to the Abbey of Polirone (P. Morgan library). During the 13th century, Italian illumination in the large university towns of northern Italy developed freely and in a manner quite its own. Legal text-books, Bibles, etc., were executed and taken by the students all over Europe. Moreover, the 13th century produced a new type of book, the immense choir-book, which was everywhere used at church services. In general, large miniatures are rare in Italian illuminated mss. Most have only historiated initials, but these are drawn out to great length and spread out over the margins in branch and leaf work. Drolleries were added very early, so that one feels inclined to assume that they made their way to the North from Italy. All this, however, does not exhaust the importance of Italian miniature. Just as in mural and panel painting, Italy was foremost in diffusing the Byzantine style.

We must not overlook the immediate influence of the Crusades in causing an interpenetration of the Western and Byzantine elements. In the Latin kingdoms of the Orient, there were executed for churches and princes magnificent mss. in which such a mixture of styles was inevitable, e.g., the Psalter of Queen Melissenda of

Jerusalem (British Museum), the Missal of the Holy Sepulchre church at Jerusalem (Paris), and many others. Similar works probably emanated from those districts of Italy which were particularly exposed to Byzantine influence. We may, perhaps, put in this class the Missal at Madrid. A similar mixture of style is evident, in a much coarser form, in the Epistolary, written in 1259 at Padua (cathedral treasure). About 1300 a large number of Byzantine illuminations were produced at Bologna, which are distinguished by copious border-decoration, with figures in the pseudo-classic style. Splendid works of this kind are the Bibles at Paris (B.N. Lat. 18) and at the British Museum (Add. 18,720).

During the 14th century, throughout Italy's busy scriptoria, as at Naples, where French influence is noticeable, numerous mss. rich in miniatures were produced (Bible, subsequently Leo X.'s, now Berlin, Kupferstich-Kabinett). Only rarely can we connect miniatures with the artists who painted on panel. A Virgil in Milan and the Ufficio di San Giorgio in the archives of S. Peter at Rome, are assigned to Simone Martini of Siena.

Miniature Since the 15th Century.—Many illuminated mss. of the later 15th and 16th centuries surpass in wealth of pictures and magnificent embellishment, even the works from the time of the duke of Berry. Their place is finally taken in the 16th century by black and white. The splendid miniatures of the 15th and 16th centuries are, like those of the preceding period, chiefly destined for princes and great courtiers. Three large centres of production are prominent: Flanders (Ghent, Bruges); France (Paris, Tours); Italy (Florence, Ferrara, etc.). Illumination in this period acknowledged no restriction on its choice of subject. The Books of Hours, indeed, still played an important part, but, besides these, there were profane mss. of an incredible variety, among which the Chronicles on the one hand, and the Romances on the other, are prominent.

Flanders.—In the generation following the van Eycks it can only rarely be proved that painters on panel had a hand in illumination. We know a number of miniaturists from their works or from documents, e.g., Jean le Tavernier, Willem Vrelant, Loyset Lyédet, Philippe de Mazerolles, the Bening family. About the middle of the 16th century the activity of the Flemish scriptoria seems to have died out. It is important to note Simon Marmion, unsurpassed in landscape (Book of Hours, British Museum Add. 38,126). A master belonging to the circle of Roger von der Weyden is called after the Romance of Girart de Roussillon Jean le Tavernier, who adorned the Conquêtes de Charlemagne executed for Philip the Good (Vienna, Staatsbibl. 2,549). His second masterpiece, the Chronicle of Hennegau, is at Brussels. (Brussels, B.R. 9,066.)

France.—The production of French mss. during the 15th century will not bear comparison with the Flemish. In connection with the mss. of the duke of Berry, there is the Bedford Missal (British Museum) and the Salisbury Breviary in Paris, with its numberless miniatures. About the middle of the 15th century Jean Fouquet, the most important personality among the French miniaturists, makes his appearance. He died about 1480, at Tours, where he had lived before and after his journey to Rome (between 1443-47). Attested works of his are parts of the *Antiquités Judaïques* at Paris, and the miniatures cut out from the *Heures d'Etienne Chevalier* at Chantilly. Fouquet's art has a touch of the Renaissance which otherwise shows affinities with Flemish naturalism. The miniature survived under Francis I., and even into the time of Louis XIV.

Germany.—In Germany, in the 15th century, illustration passes a humble existence in monasteries and scriptoria which engage in large-scale manufacture of mss. (Diebold Lauber in Hagenau). In contrast with this mass production, there are the splendid mss. of the emperor Maximilian. The finest is the superb border, executed by Dürer and other great German artists, in a copy of the Prayer Book printed by Schönsperger (Munich, Staatsbibl. and Besançon).

Italy.—In Italy the renaissance in the mss. begins with the introduction of the *scrittura umanistica*, which goes back to the model of the fine Italian mss. of the 11th and 12th centuries,

from which was also taken the scroll-work design in the frames enclosing the pages of text. Illumination does not really flourish until the middle of the 15th century, when there arose, almost always in connection with the luxury of courts, a number of studios which created a new style and new decorative forms. As in Flanders, the artists are seldom identical with the painters on panel, although, for example, the great art of Mantegna is reflected in miniature. In northern Italy, Milan and Verona were two of the centres. A masterpiece is the Book of Hours of Bona of Savoy, widow of Galeazzo Maria Sforza, duke of Milan, which afterwards came into the possession of Charles V. (British Museum Add. 34,924). In the Ferrara school, where a number of miniaturists worked for the ducal family of Este, Taddeo Crivelli takes the first place (Borso d'Este's Bible, 1455-62, Modena). The most important miniaturist under Borso's successor, Ercole I., is Martino da Modena (Ercole I.'s Breviary at Vienna). Miniature-painting in central Italy was chiefly concentrated at Florence; Francesco d'Antonio del Cherico, with Attavante degli Attavanti, were the two chief miniaturists. (See PAINTING; MINIATURE PAINTING; BYZANTINE ART; BOOK; BIBLE; MANUSCRIPT; PALAEOGRAPHY.)

BIBLIOGRAPHY.—The most convenient book of reference is: H. Omont, *Listes de recueil de facsimilés et de reproductions de mss. conservés à la Bibl. Nat.* (2nd ed., Paris, 1912). Numerous articles of the highest importance are scattered through the scientific periodicals.

(A. Hf.)

ILLUMINATI (Lat. *illuminare*), a designation in use from the 15th century, and applied to, or assumed by, enthusiasts of types distinct from each other, according as the "light" claimed was viewed as directly communicated from a higher source, or as due to a clarified and exalted condition of the human intelligence. To the former class belong the *alumbrados* of Spain. Menendez Pelayo first finds the name about 1492 (in the form *aluminados*, 1498), but traces them back to a Gnostic origin, and thinks their views were promoted in Spain through influences from Italy. One of their earliest leaders, born in Salamanca, a labourer's daughter, known as La Beata de Piedrahita, came under the notice of the Inquisition in 1511, as claiming to hold colloquies with our Lord and the Virgin; having high patrons, no decision was taken against her (*Los Heterodoxos Españoles*, 1881, lib. v.). Ignatius Loyola, while studying at Salamanca (1527) was brought before an ecclesiastical commission on a charge of sympathy with the *alumbrados*, but escaped with an admonition. Others were not so fortunate. In 1529 a congregation of unlettered adherents at Toledo was visited with scourging and imprisonment. Greater rigours followed, and for about a century the *alumbrados* afforded many victims to the Inquisition, especially at Cordova. The movement (under the name of *Iluminés*) seems to have reached France from Seville in 1623, and attained some proportions in Picardy when joined (1634) by Pierre Guérin, curé of Saint-Georges de Roye, whose followers, known as Guérinets, were suppressed in 1635 (Hermant, *Hist. des hérésies*, 1717). Another and obscure body of *Iluminés* came to light in the south of France in 1722, and appears to have lingered till 1794, having affinities with those known contemporaneously in this country as "French Prophets," an offshoot of the Camisards. Of different class were the so-called Illuminati, better known as Rosicrucians, who claimed to originate in 1422, but rose into notice in 1537; a secret society, combining with the mysteries of alchemy the possession of esoteric principles of religion. Their positions are embodied in three anonymous treatises of 1614 (Richard et Giraud, *Dict. de la théol. cath.*). A short-lived movement of republican freethought, to whose adherents the name Illuminati was given, was founded on May-day 1776 by Adam Weishaupt (d. 1830), professor of Canon Law at Ingolstadt, an ex-Jesuit. The chosen title of this Order or Society was Perfectibilists (*Perfektibilisten*). Its members, pledged to obedience to their superiors, were divided into three main classes; the first including "novices," "minervals" and "lesser illuminati"; the second consisting of "freemasons," "ordinary," "Scottish" and "Scottish knights"; the third or "mystery" class comprising two grades of "priest" and "regent" and of "magus" and "king." Relations with masonic lodges were established at Munich and Freising in 1780. The order had its branches in most countries of the European continent, but its total numbers never seem to have exceeded two thousand. The scheme had its attraction for literary men, such as Goethe and Herder, and even for the reigning dukes of Gotha and Weimar. Internal rupture preceded its downfall, which was effected by an edict of the Bavarian government in 1785. Later, the title Illuminati was given to the French Martinists, founded in 1754 by Martinez Pasqualis, and to their imitators, the Russian Martinists, headed about 1790 by Professor Schwartz of Moscow; both were Cabalists and allegorists, imbibing ideas from Jakob Boehme and Emmanuel Swedenborg (Bergier, *Dict. de théol.*).

See (especially for details of the movement of Weishaupt) P. Tschackert, in Hauck's *Realencyklopädie* (1901); and on the general subject, W. T. Whitley, art. "Enthusiasts, Religious," in Hastings, *Encyclopaedia of Religion and Ethics*.

ILLUMINATING ENGINEERING, term now used to denote all applications of natural and artificial light in the service of mankind. Progress in Great Britain since 1910 is largely the

result of the formation (in 1909) of the Illuminating Engineering Society, in which makers of lamps and lighting appliances and users of light co-operate; all illuminants are represented and all aspects of the subject, economic, hygienic and artistic are considered. A similar body, the pioneer in this field, has been in existence in the United States since 1906, and corresponding bodies have been formed in Germany (1913), Austria and Hungary (1925), Japan (1915) and Holland (1926). In Germany two additional societies operating in Karlsruhe and in the Rhine-Westphalia district have also been created. Attention has been paid to illumination at many international congresses, thus promoting the exchange of views between experts in different countries. The reorganization of the International Photometric Commission, founded in 1900, as the International Illumination Commission was stopped by the World War, but a fresh start was made in 1921, and the leading countries are now represented with national committees for the respective countries. (See J. W. T. Walsh, "International Co-ordination in Illumination," *Trans. First World Power Congress* [1924], vol. 3.) Much has been done towards standardization and agreement on common principles. Definitions of the main photometric quantities have been adopted, and a more extended series of definitions, symbols, etc., framed, while sub-committees to deal with lighting legislation, automobile headlights, etc., have been formed. At the sessions held in Geneva in 1924 and at Bellagio in 1925 further activities were initiated and the commission is extending its work to deal with various practical problems. Evidence of further progress in this direction was afforded at the International Illumination Congress held in the United States in 1928.

The International Candle.—A noteworthy step, dating from 1909, has been the agreement between France, the United States and Great Britain and, recently, also Russia, on an international candle so that the same unit of light is now in use in all four countries; but in Germany and some other countries the Hefner candle (equal to 0.9 international candle) is still in use. Preservation of the unit of light is now effected by the exchange of specially prepared electric lamp-standards between the official laboratories in the countries concerned. Meantime experiments are being made with a view to evolving an absolute standard of light, e.g., one based on the maintenance of a "black body" at a specified temperature.

Progress in illumination has kept pace with this advance on the scientific side. Electric lamps, filament and arc, have been developed (see **ELECTRIC LIGHTING**). In the field of gas lighting there has been steady progress in design, one instance being the smaller and more compact forms of high-pressure gas lamps, now rated to give 60 candles per cu.ft. of gas consumed. In low-pressure gas lighting the use of superheated clusters of inverted mantles has made possible a gain in efficiency estimated at 30%. The distribution of the light from a number of smaller mantles is considered an advantage, and the smaller types of mantles are the most durable. Cluster-lamps giving up to 2,000 c.p. are now available.

Theory of Radiation.—Researches into the theory of radiation and the principles underlying illuminants provide a clearer understanding of the luminous efficiency theoretically obtainable. Thus a light source yielding visible white light and no non-luminous vibrations would operate at approximately 26 c.p. per watt, whilst if the light were confined to the most efficient yellow-green section of the spectrum as much as 60 c.p. per watt might be obtained. But in the case of new illuminants efficiency is not the only consideration; such special qualities as the colour of the light (as in the neon lamps) or the nature of the supplementary invisible radiation (as in the quartz tube mercury vapour lamps) may be of even greater importance.

Reflectors, etc.—The design of shades, globes and reflectors for use with lamps has assumed great importance. By suitable design of a reflector the distribution of light from a source may be altered within wide limits. Thus extensive, intensive and focusing forms of reflectors yielding standard curves of light distribution have been designed, and corresponding rules for height and spacing, designed to give even illumination on the working plane have

been derived. In most cases a shade or reflector is designed to direct most of the light downwards, where it is chiefly needed. But other cases occur, for example in shop window lighting and the illumination of large posters, etc., where reflectors are so designed and spaced as to yield an illumination over an extensive vertical area. Another function of shades and reflectors is to screen the actual source of light from the eye. Even when only vacuum metal filament electric lamps were available the glare from exposed filaments irritated the eye and prevented it from registering the full effect of the illumination provided. In the case of the gas-filled lamps, with their very much brighter filaments, the need for scientific screening is yet more evident. Hence in the leading stores concealed lighting of show-windows, with the light thrown on the goods but the sources concealed from the eyes of observers, is coming to be regarded as the correct method; and it is only in the smaller shops that exposed sources of light are still too frequent. A special instance of a concentrating reflector is to be found in the "floodlighting" units, consisting of an incandescent lamp with a special "bunched" filament at the focus of a parabolic mirror. Such units are miniature searchlights and are now being used to illuminate the façades of buildings. The design and application of such units have been dealt with fully in a paper recently read before the Illuminating Engineering Society by W. J. Jones.¹ With the searchlight proper, using an arc, the dimensions of the source of light can be much reduced and a beam of many millions of candle power attained.

Searchlights.—A notable advance during the World War was the design of searchlights using cooled electrodes leading to a yet smaller and more brilliant source and corresponding greater concentration. The cooling has been effected by two distinct methods, a blast of air and a spray of alcohol; in both cases a very substantial increase in beam-candle power for a given current consumption was obtained.² The brightness of the crater in such cases has been estimated at 200,000–300,000 candles per sq.in., as compared with 85,000 c.p. per sq.in., in the case of the ordinary searchlight. In Germany, Lummer, working with an arc operating in a chamber under an air-pressure of 22 atmospheres, is said to have attained the enormous brightness of 1,500,000 candles per sq.in. But this method has apparently not yet reached a practical stage.³

An apparatus capable of projecting pure spectrum colours on the stage, which is in effect a giant spectroscope, has been designed. By the Mutochrome projector,⁴ a series of superimposed patterns can be projected on the screen and the colour of each varied at will. This is likely to prove of considerable value to designers of wallpapers and coloured fabrics, as well as having a possible application for the projection of luminous scenery on the stage.

Artificial Daylight.—Efforts have also been made to provide "artificial daylight," i.e., to correct the light from artificial illuminants and render it equivalent to normal daylight for the matching of colours. Two methods of effecting this correction have been applied. In the Sheringham unit the light from a gas-filled lamp is reflected from an upper surface coated with a pattern of green, blue and a small amount of yellow in suitable proportions. In the system usually associated with the name of F. E. Lamplough the light is filtered through a combination of tinted glass. In either case the efficiency of the apparatus is necessarily low, 60% or more of the original light being lost in making the correction. But the advantage to firms in the dyeing industry and others concerned with delicate colour-matching of having an invariable artificial light, independent of the wide variations of natural daylight, is very considerable. Attention has also been devoted to the production of fittings yielding light visually similar to average daylight, but less completely corrected. Such lighting units which have a relatively high luminous efficiency are recommended for use in picture galleries, shops devoted to

coloured objects, etc., and in cases where daylight requires frequently to be supplemented by artificial light. It is suggested that such light is less fatiguing to the eyes than entirely uncorrected artificial light.

The psychological and other problems attending the lighting of streets, schools, factories, shops, etc. and the avoidance of eye strain in cinemas, the importance assigned to proper lighting in factories, and the interests of health, safety and efficiency of work have been investigated by the Illuminating Engineering Society and Home Office committees.¹ Evidence on lighting requirements in factories has been collected from many different sources, and records of over 4,000 tests of illumination in different factories have been presented. The minimum values of illumination in the interests of safety (0.25–0.4 ft.c.) are established. Recommendations on the subject of avoidance of glare, flickers and inconvenient shadows have been made, and the illumination required for carrying out work is demonstrated to be not less than three foot-candles for fine work and five foot-candles for very fine work. Consultations with various joint industrial councils are now proceeding with a view to determining what constitutes suitable and adequate lighting for processes in their respective industries.

In the United States detailed codes of industrial lighting have been adopted in various States. In principle these follow closely the recommendations of the British committee. Methods of grading various lighting units according to the degree of "glare" are outlined, and the positions which may safely be assigned to such units in a workshop are tabulated. The codes also contain standards of the illumination requisite for various processes, a distinction being drawn in the most recent codes between the minimum value desirable and higher values recommended in the interests of economic production. A considerable amount of research has been devoted to the relation between conditions of illumination and efficiency of work. Thus it has been shown by Dr. Ives of the United States public health service that the despatching service in post offices was expedited and rendered more accurate by better conditions of illumination;² tests in laboratories in Germany have likewise revealed a close connection between illumination and many processes involving exact vision and manual dexterity.³ The subject of industrial lighting has likewise been studied by the International Labour Bureau of the League of Nations in Geneva.

Particularly difficult cases of industrial lighting also form the subject of study by the committee on illumination, working under the Department for Scientific and Industrial Research, on which eminent architects and medical men, besides lighting experts, are represented. It has published several informative reports, amongst which that dealing with the lighting of printing works has excited special interest. In this enquiry the important conclusion was reached that full efficiency in type-setting by hand is attained only with an illumination of the order of 20–25 foot-candles.³ This committee also deals with all enquiries bearing on illumination received from the various Government departments. In connection with this and other aspects of lighting, increased attention is now being devoted to the hygienic side, and at the International Congress for the study of industrial hygiene held in Geneva in 1924 a special resolution was passed accepting good illumination as of equal importance with heating, ventilation and sanitary conditions in the interests of health and safety.

Standardization.—Standardization in various fields is being dealt with by various sub-committees, working under the British Engineering Standards Association, which have prepared specifications on the performance and dimensions of electric lamps, and have also issued standard specifications for portable illumina-

tion photometers,¹ reflectors used for industrial lighting,² street lighting³ and illuminating glassware.⁴

Traffic and Lighting.—Experience during recent years has shown that the questions of lighting and transport are closely related. With the progressive increase in the volume of fast-driven motor traffic the necessity for good public lighting has become even more urgent than in the past; and the increase in the number of street accidents year by year has drawn public attention to the importance of the question. A new problem is presented by the lighting of arterial roads connecting cities. These routes are primarily intended for fast motor traffic and their utility will not be realized fully unless adequate artificial lighting is provided, enabling them to be used with safety by night as well as by day. Special methods of illuminating such routes are now the subject of consideration. Light is being used to an ever increasing extent as an aid to the guidance of traffic and, on the initiative of the Association of Public Lighting Engineers a resolution was recently passed advocating standardization of traffic signs and signals.⁵

Many devices eliminating glare from powerful automobile headlights have been suggested, some of the most promising based on the limitation of the main portion of the beam below a certain horizontal plane so as to avoid the direction of rays into the eyes of approaching drivers or pedestrians. But the most hopeful solution lies in the provision of better public lighting, which would render very powerful headlights unnecessary. Progress in these various directions has been aided very greatly by the introduction of simple forms of instruments for measuring illumination of which quite a variety of types is now available. The information acquired in this way has been very helpful in framing recommendations for the degree of illumination necessary for various purposes.

ILLUSION, the experience and the result of misconstruing or misinterpreting some real sense stimulus or stimuli, as when a wax figure at Madame Tussaud's or similar exhibitions is mistaken for a real policeman, or when a piece of suitably modelled plasticine is mistaken for a sausage. Something is actually there to stimulate the senses, and the sense experience itself is produced in a normal manner, but, owing to established habits of rapid association or the temporary "set" of the mind, the observer mistakes the thing for something different. Many optical and other illusions are perfectly normal and can be experienced by a large number of people at the same time. This happens, for example, at the familiar entertainments consisting of juggling and conjuring tricks, also ordinarily in public places, thanks to the luminous "moving" advertisements which make modern civilization so gay and dazzling at night. The normality and indeed the inevitableness of so many illusions constitute one of the serious problems in any attempt to vindicate the validity of human knowledge. (See HALLUCINATION; ABNORMAL PSYCHOLOGY; PSYCHOLOGY [and the bibliography given there]; KNOWLEDGE, THEORY OF.)

which tell a story. These pictures are bound by conventions to such a degree that the individuality of the artist is lost in the imposed formula. There is no drama as we understand it. An exalted personage is simply represented proportionately larger than his fellows. Attitudes and gestures are prescribed. Yet they tell a story and to that extent they are illustrations, but they are more than that: they tell the story of a whole people, of a people's faith and hope and life. They are generic. They do not deal with incident. If one finds two people playing a game, it is an incident in the whole life of all the people and tells the story of that people and a game—not of two definite individuals at a moment in one special game with the specific incidents that attend that particular moment among all others. An illustration is a story-telling picture of a specific incident and its weakness lies in this very thing: that the greater idea is often secondary to the less. Yet in most illustrations, of fiction especially, the picture deals with the lesser idea.

The illustrator's work is the complement of expression in some other medium. A poem can hardly exist which does not awaken in the mind at some moment a suggestion either of picture or music. The sensitive temperament of the artist or the musician is able to realize out of words some parallel idea which can only be conveyed, or can be best conveyed, through his own medium of painting or music. Similarly, painting or music may, and often does, suggest poetry. It is from this inter-relation of the emotions governing the different arts that illustration may be said to spring. The success of illustration lies, then, in the instinctive transference of an idea from one idea to another; the more spontaneous it be and the less laboured in application, the better. The mind must be aware of an underlying unity, yet without being intellectually conscious of it.

Greece and Rome.—Proceeding another step, to the decorations on Greek vases, we have a more decided association between literature and pictorial art. We have a great legacy of poetry, picture and sculpture derived from Greece. There was a great theme—the heroes, the gods and demi-gods. The many legends and stories made them living beings, understandable because of their human qualities, inspiring because of their magnificence. These extraordinary myths filled the minds of all the people, for the story tellers went about reciting to those who could not read. All of the people perceived splendour in these heroic adventures—physical adventures, of course—and they magnified their heroes into an ideal.

A poet or an artist appears to be an individual, developed by his race, whose business it is to go out and see beauty and come back and tell about it. His business is to go out and see with the eyes of his own people, of his own time, of his own country and to show to them the things they love or reverence in a manner intelligible to them.

To the Greeks, the hero was a glorious human creature; inevitably their artists were moved to sculpture and to an ideal, an ideal which sought to show how magnificent man might become. Their honest service in this respect to their race leaves them unrivalled through all the centuries that have elapsed. Inspired they surely were, but inspired wholly by the passionate impulse of their time. When the draughtsman came along to decorate the vases of his people his motive was usually a simple association of those same heroes, gods and goddesses in one picture, containing, indeed, the essential surroundings, but always governed by the racial delight in perfected humanity. The poets told the same stories, so that to-day the sculpture, the picture and the play or poem mutually illuminate one another. Though not designed to illustrate any special line or poem, the pictures become illustrations of the finest type, generic rather than specific.

The Roman artist began to see landscape and introduce it into his wall paintings, usually to increase the apparent size of the garden upon whose enclosing walls his pictures were usually painted.

The Christian religion provided the next tremendous impulse toward visual art. Again all eyes were turned in one direction, all aspirations toward one glory and all reverence toward the

sacred personages who suffered that they might bring to the humble masses no less than to the exalted individuals the wonderful message. For the Founder of the Christian religion had made the multitude worthy in its own eyes. He proclaimed their kinship with God and convinced them that they were beloved children of a loving, omnipotent Father in Heaven with Whom they should dwell, after this life of trial, in glory forever.

To a people treated like beasts of burden, driven and trampled upon, such a revelation was of tremendous import. The individual's right to prosperity and happiness here in this world naturally had not yet occurred to the many. They were taught that resignation, contentment and labour for their masters was the service for which they should receive the Divine reward in Heaven. The poet and the artist, born and bred of the peoples under that impulse, did as they were bound to do. They showed to the multitude the thing it revered and longed to see. The artists of that day were the sons of the multitude, and sharing in the beliefs of that multitude. They set forth in their paintings that which filled their own hearts no less than the hearts of all men moved by the same revelation.

Gradual Development.—The whole thing became a driving desire to make visible a great drama. They began to perceive the possibility of the dramatic composition which preserved the just proportions, and yet permitted the emphasis to fall upon the important incident in the picture which is known as the "centre of interest."

Composition was not unknown before this time, but it was a composition of design entirely, owing nothing to tone and very little to light and shade. Rarely, in even the best examples of vase paintings, is great action attempted. Generally, the figures express themselves in simple gestures, so that no intolerable suspended motion is noticeable. The Italian painter, finding himself confronted by the necessity to depict dramatic moments full of activity, devised new methods of composition. The suspended moving body or drapery, conforming to realism, is made to flow upon a line in the composition in such a manner that it is no longer a painfully maintained posture, but a part of the rhythm of the composition, an expression of extreme grace and of beauty.

Year in and year out that development went painfully on. They strove mightily, those men; they worked to exhaustion. They had but little to work with, compelled as they were to invent their own materials, colours, brushes, whatever they needed. In the early years of the attempt to reveal to their own eyes, and those of their people, a vision glowing of the spirit, they had nothing with which to do it. They could not draw, they could not paint; they recognized perspective but vaguely and they lacked general knowledge. But they had a story to tell in pictures and they themselves lay under an urgent need to see the visualization of their own dream. It was a story of the spirit—which is beauty. They painted a message from heart to heart. Any man, standing before these old treasured pictures, who is unable to let them appeal directly to his emotions, as is the case with music, can never hope to see them nor to understand why they are treasured.

As time went on jealousy and rivalry arose. The secrets of the craft were carefully guarded. A painter of great ability was crowded with commissions, which were often commands. Daylight was precious. Every moment was needed upon his compositions. He surrounded himself with pupils and from among these he chose helpers according to their ability. Thus came into existence the journeyman-apprentice, who reached his greatest development during the last century. He was the pupil of great technical skill, direct observation and little imagination. He was sent out to get facts. A group of trees was needed for some part of an important composition. He was sent out to make a study of it—not only the group of trees with meadow and clouds, but accurate information of branch and twig, with the pattern of leaf, the modelling of the trunk and the facts about the spreading roots with the plants growing between. He came back with definite knowledge, precise information which the master painter used as he saw fit. He chose what he needed, simplifying it into harmony with its importance in the picture, discarding what was

irrelevant. The master painters were great illustrators, and it is from among them that arose the immortal few who are known as the Old Masters, because of the grandeur of their vision and the splendour of their expression of it.

And then the association of picture and its subject-text bound in the same volume came into being in the form of the illuminated manuscript. The same story and the same sincerity inspired these little pictures, truly works of art, though small and painted upon the page of a book and definitely designed to harmonize with the page, and with the elaborate initial letter of which, frequently, they were a part. Some of them were superb masterpieces. The size of a picture matters little. If, however, the subject idea is unworthy of a great effort, the picture made too large, and with the inevitable elaboration, appears even more trivial than if proportioned appropriately.

Portraiture.—In ancient portraiture, incidental to all this early art, one seems to observe evidence that likeness primarily was sought. In Egypt imposed conventions prevented any real development of characteristic portraiture, or perhaps the artist was so trained to convention that it was not possible for him to free himself from its influence. Nevertheless, there are examples, small statues and statuettes, which are portraits of individuals, of definite character. Greek portraits, however, painted on small panels, seem meagre studies of character, but were probably sufficiently good likenesses. During the Renaissance portraiture came very much alive, emerging from hampering tradition and convention, until, in the 17th century it reached a magnificent expression. It became a realistic study of character, which was food for imagination. Painting his portrait, the artist came to know the man. He found, as he and everyone else already knew, that men are very much alike, and entirely different, in real life; he discovered that it could be expressed in art. Self-defence had taught every one to discern the mood of another. Every one knew at once whether another was about to strike, to smile, to speak a word of kindness; now the artist began to discover it in terms of his craft. He discovered that he could envelop the characters of his picture in an emotional atmosphere. He perceived in the hat and gloves left by his sitter on chair or table a likeness to their owner and that if they were used in a picture these adjuncts would have something to say as to the character of the man. When he came to paint the genre (*q.v.*) picture, he saw to it that the things belonging to his subject character were exactly the things with which this individual would inevitably surround himself. That is a part of illustration which requires imagination, knowledge and understanding derived from close and habitual observation. Imagination here is spiritual vision. This vision once possessed, aided by all his various funds of knowledge, the artist will perceive how an individual whose character he has studied and come to understand will behave in a given situation. It amounts to a vision of orderly events inevitable for that individual.

The religious story had been told, and while it continued to appear, and still often does, it was no longer in demand to the same extent. The artist was free to choose his subjects where he would, to descend gradually from that height to which the hunger, need and will of his race had driven him. Perhaps the most impressive example of this hangs in the museum of the Louvre. Huge paintings tell the story of the marriage of a man and a woman, but the man was king of France, Henry IV., and the woman a princess of Italy, Marie de' Medici. To the consciousness of that time such nuptials were great and impressive affairs, symbolic and resplendent with the grandeur of nations. Realistic pictures, however gorgeous, would be merely pictures of the pageantry of the event. The artist's task, however, was to make the significance of the event immortal.

Here is another instance where the artist was in accord with the convictions and motives of his time. He may have hated that particular king, but he and all men worshipped kings. To him and to all men this particular episode was of divine moment and significance. The gates of heaven opened; gods and angels with all their attributes of Power, Principalities and Virtues were present at the ceremonial, bearing aloft, in order to magnify those two

royal mortals above mankind, the insignia of their isolation. That is what the pictures tell us.

To this artist, learned in his craft, it was not a very troublesome problem. The art and science of composition taught him how to use every incident in his pictures—numberless attendant figures; the profuse ornament of landscape and cloud; luxurious draperies, architecture, banners, armour—extraordinary in their number, variety and form; to exalt the two principal personages upon the apex of his design and convey that, while in the midst of many, they were solitary, unapproachable, beings apart. Previously he had painted many portraits, landscapes, studies of all kind in astonishing numbers. He had used his countless studies in countless paintings of every sort. He employed many hands besides his own. Nevertheless, he invented and designed his group of pictures as a whole, supervised and brought it into being. They were great inventions, for his imagination was apparently concerned with another aspect of the matter: it was busy with his audience—not in vanity, but in the *completion of his theme*. His business was to convey an idea to the world. He was not realizing a vision of his own and so, in his imagination, he viewed his growing designs with the eyes of the world, inventing his means step by step. Whether he, specially, was hated, whether he was bitterly regarded by jealousy are things aside. His world was with him in this task which it had commanded. He worked for a great audience, for the generations, for all time. He was not at the mercy of the turning page descending into oblivion with a trivial story.

Later Development.—It is not to be understood that no great works of art have occurred since that time. But the times were changing. Democratic ideas began to seep in and spread. New seas and continents were being discovered. Shipping, commerce, international intercourse vastly increased. Wealth was increasing rapidly until it became more than a motive, an ideal. The artist, of necessity sensitive to the psychology of his time, inevitably sensed this ideal. Being no longer under command of church and noble he was free to sell his talents to the highest bidder. He did and became often both politician and courtier, frequenting and contriving that he might frequent, the places whence commissions came. For the palaces of the rich, artists painted huge compositions, many of them splendid but of frivolous thought upon tawdry subjects. Not all of them did this, for some were the spiritual descendants of the great masters; they went back to the country-side. There they painted pictures so full of charm, of beauty and of poetry that they still hold our wonder.

The religious subject in pictorial art is not of paramount importance, nor is any subject. War and the ambitions of men have provided the opportunity for many great paintings. As to the written title of a picture, it is a mere label. The subject is what the passion of his race has taught the artist to think about it. Because the poet, the artist and the inventor—which is to say the poet—is born supremely sensitive to racial motive, he has led in thought and has imagined into material existence the things of its need and desire.

Imagination is the power of creative vision which gives direction to intellect. It is the business of intellect to find means whereby this vision is given material existence. In finding these means intellect must refer again and again to imagination for new directions until the dream comes true.

There is another sort of imagination: a primitive imagination busy with fears and reprisals. It is the mother of superstition and has troubled the mind of man with a terror of natural phenomena. He cowered before the wind, retreated in dismay before the rising waters in the spring-time and shuddered at thunder, whispering that it was the voice of an angry god or the roar of some demon. As he grew weary of his fears man developed a courageous creature who was not afraid to take his life in his hand, to go out and see; one who would be satisfied with nothing but the truth, who would not stop till he knew it. He went out upon his mission and came back and reported that these things are inevitable results of natural law—dangerous but not malignant. Having begun, he can not stop, for the will of the race is that he must go on. We call him the scientist; his reports are

called scientific facts; but scientific fact is the statement of the operation of natural law and natural law must be obeyed in art as well as in life.

Learning to Draw.—If any one turns to these pages in the hope that he will find a suggestion how to proceed, let him remember that, like the primitive artist, he has already in childhood scratched the uncertain image upon a slate. Let him take as his model the labour of the artist from that remote primitive time until he attained to his greatest stature.

First he learned to draw a figure; then he strove to make that figure beautiful; then, expressive. He laboured with nature to learn the laws of composition. He came into the lamplight and went out into the sunshine to know about light and shade. He studied atmosphere and the moods of nature. He learned to present an individual with his characteristic possessions and the psychology of his relations with others. He mastered these things thoroughly—then dismissed the troubles of ignorance and painted his picture. This impersonation of all artists lived for many centuries through all the turmoil of the great march of mankind. He is immortal. We are part of him. Without the understanding which came through his long life we can do little. His life has left its record. Learn to know it.

The laws of composition are written down. Learn them. The scientist has sought till he found the laws of light; he has arranged the simple formula of perspective; these are material means which nature provides and imposes. We must know them.

The artist has always told a story of some sort; let it be the simple statement that "Silver is Beautiful with Blue." That is theme enough for a masterpiece of colour. Perhaps it may be that "A Tree against Clouds is a Beautiful Design." That is theme enough for a masterpiece in black and white.

The Work of the Illustrator.—If stories are told in words, however skillfully elaborated and explained, one must refer to one's own observation and experience to perceive the motive of the author. That reference to the writer's observation, conveyed in words of one's own experience and vision, is generic illustration. Many persons have had no opportunity for parallel experiences with the author. Many have not the power of original observation. But the majority can associate the two when someone shows them how. That is the work of the illustrator.

No modern illustrator worthy of the name fails to realize that he is working for the people who buy that medium of distribution of story and picture which we call a "magazine." He is paid by so small a fraction of the amount expended that his work is bought for virtually nothing. He is under command of the whim of no one man. But he is under command. So were his forbears. They were under command of the whim of power. One of the greatest, a *sculptor*, was commanded by peremptory authority to *paint* the ceiling of the Sistine chapel. He spent three years lying on his back to work upon it and eased his bruises by writing plaintive sonnets and querulous letters to his father complaining that the work was vile and would not be accepted.

We of the present are under command only of the necessity imposed by a vast organization of which we voluntarily form a part. That the story and picture may reach the millions who wait upon a certain day, a great, complicated organization of men and machines must work constantly and without interruption. The illustrator becomes a part of that organization when he accepts a commission. He does not have to accept it; he may refuse; but once undertaken it must be done within a given time that all the processes may function at their best and the printed work delivered where and when it is expected. This is not arbitrary; it is inevitable.

Consider the editorship of the grand epoch of art. The labour of years was unveiled—the cold churchman stalked before it seeking heresy. The partisan peered into its corners for offence. Woe to the poor artist if either was found! The editor of to-day is all concern in his attitude toward the artist, providing a chair and kindly words; this is found to be more humane than the accusation of heresy and a cell under the leads.

The work of an illustrator is of the present, now. Art is of its

own time, looking forward. It derives its knowledge and power of comparison from the past, but its real inspiration from its own time. It is a sad thing to find an artist to-day so possessed with admiration of one of the great of the past that he endeavours to depict his own times, not as the dead genius might do now, but as he did then: whispering an unintelligible echo of stalwart tones reverberating with the meaning of the past. Times have changed. Little of the expression of the past applies to the present. There is no motive now, in any one direction, to impel a living pictorial art.

Mankind is making machines, discovering new laws and forces, applying them to his entertainment. Art, too, is an impulse of nature and it also is being used for entertainment. Born of the multitude, the artist must serve the multitude; if it so commands, he serves by leading it. And if it should have a great dream he must present it pictorially. If the public desires tawdry decorations, he will be bullied or cajoled into making them. If it demand entertainment he must help provide it. Increasingly specialized, used for meagre ends, he has therefore almost ceased to be—sleeping, perhaps, to be awakened at the call of a new need. Buildings go up and are torn down after such brief existence that mural paintings are but vaguely used—the easel picture has little reason to be—it is too heavy for our temporary walls. The exhibition gallery continues to house for its appointed time the dwindling work of the journeyman-apprentice. The real place for pictures seems to be the page of the magazine. The times demand it; it appears inevitable. Possibly this is only a phase.

It is the illustrator's business to give his best. The public will not help him, because it cannot. It behooves the illustrator to become a scholar; to know; to put all he is and has into his work; to study his story, not merely read it. He must do it alone, for himself; no one cares. If his work is up to publishing standards in craftsmanship it will be used. Editors will not help him with drastic criticism, or demand his best. He must work alone and for himself—that is what "art for art's sake" means now. It is true he will be paid a handsome sum; but it is also true he will be paid just as much for work not his best. Here is a spiritual problem. He must do his best, for himself, alone, rejoicing if three persons in the million realize it. He must be a strong man.

The Illustrator's Problems.—To-day the conditions are utterly different from any hitherto confronting the artist. Instead of some single motive he has many. Wide spread democracy encourages everyone to get for himself whatever he most desires. Universally that is wealth. Everyone works for wealth and in his leisure seeks amusement, entertainment, demanding of the arts that they provide it.

If a universal motive is a compelling theme for the artist then this universal struggle for wealth should surely supply it. If it is, then it appears to have developed, by almost equally universal patronage, a new art: the motion picture. It may be significant that the most popular, and therefore successful, motion pictures dwell lavishly upon great wealth, the effort to gain it—within or without the law—or else upon broad comedy. The motion picture might be regarded as illustration in its most elaborate form; but it is not. It is an art alone, and like all arts, best when it tells its own story in its own terms, borrowing from no other.

In the life of to-day there is another new thing. We are conscious of enormous forces that can be made to obey. We are aware of tremendous machines developing an energy equal to an army division, to several army divisions! We have ceased to fear the forces of nature and we have learned that if we obey natural law we may use the unlimited power nature's forces supply. These huge machines move in simple rhythm; ponderous creatures, impersonal, obedient, whose soulless grandeur has given a character to the times. Their significance is power. Some of us shudder at it, some exult, and it moves deeply the emotions of others.

In the presence of these new beings, made by the hands of men, traditional beauty of graceful curves, with the delicate harmony of colour, becomes a cloying sweetness, out of key. The painter has made an effort to express his sense of all this. Therefore we

have had a procession of "schools": the cubists, the futurists and many others have made efforts to get into tune with the age. The painter tried geometrical forms; he tried brutal evasions of actuality of form and colour. He sought desperate means indeed. He sought to express the thing he felt—he did not seek to find some new thing to sell. For the painter has tried to stand firm upon integrity and to be faithful to traditions.

Whenever an individual perceives a new and real thing and tells about it, immediately he is surrounded by followers, enthusiasts, incapable of, or lacking the courage of original vision, but quite able to see when shown, and courageous enough to follow. *They* are sincere. *They*, in turn, are followed by imitators. The imitator sees only the thing that has been done and he sees it but superficially, copying the mannerism more often than the manner and never apprehending the underlying motive at all. Nor does he care. His purpose is to sell what he can while the public interest in the original remains. He it is who destroys that public interest, for his stature is soon apparent, and his stuff is rejected. The pity of it is that he brings about a misunderstanding of the whole effort; a few see the work of the original while the many are informed of it only through meaningless imitations.

Modern Tendencies.—The foregoing is a bare outline of the history of illustrative art, from the first intimation scratched on stone to the present difficult situation. A few centuries ago a knowledge of the history of art was not so important to the artist. His work had to do only with his own people, people who believed as he did, thought as he did and only desired to have these things shown to them. No one knew or cared how the Jew in Palestine dressed and lived in Biblical times, so the Italian painter arrayed the Biblical characters in the Italian costume of his day. To-day we have another state of affairs altogether.

The camera has gone into every corner of the world and has brought back cold, precise facts. The reporter and the investigator have gone wherever the camera has gone; they have come home with more facts, and with explanations of the camera's pictures. This is knowledge; the newspapers and magazines send it to everybody. The important question to the artist, no matter whether he paint pictures for the galleries or make them for the magazines, is: what have this wide spread knowledge and the countless photographs got to do with *him*? Shall he go into competition with the camera? The camera in the hands of an artist-photographer is a formidable opponent. Can he meet it on its own terms, on its own ground? He cannot. In a fraction of a second it will defeat his labour of weeks.

The taste of the world demands pictures. It demands paintings, illustrations, photographs; it has seemed to declare definitely when and where it desires to see one or another. It would appear, then, that the painting and illustration has something the photograph lacks. On the other hand when people desire to see in a picture what is lacking in painting or illustration they turn to the photograph. The camera can only report what is before it; it can report with exceeding beauty, at times, but it can only report. The artist can create and he can select from the manifold beauties of nature what he will, to incorporate with his creation. To the artist then, it would seem that the deliberate message of the world appears to be that *he* is expected to create and to let the camera report.

Those artists (called inventors) having knowledge of the findings of scientists, have responded superbly to this demand and have created marvellous works. The creations of the inventors have absorbed the attention and the interest of the world almost to the exclusion of pictorial arts except where these contribute as luxurious accessories, or means of entertainment and amusement. Illustrations are seen by both the "classes" and "masses." They are seen by those capable of discrimination and of appreciation. It behooves the illustrator to respect his "audience."

Illustration may become a great art, but to become a great art it must be creative. It cannot hope to compete with the camera in the reporting of facts. It has no business with the outer shell of things at all. It deals with the spirit. Dealing with the psychological aspects is a great opportunity and a serious handicap. Pre-supposing a pictorial presentation of the relations of people, the

telling of the story is inevitable. A great and simple story, akin to truth, or a poor and trivial one, akin to meagre facts, may be told of the same incident—depending upon the insight, the vision of the artist. The nature of the story portrayed is the measure of the artist who portrays it. It makes no difference that he may be most accomplished in his craft. Though he may draw with marvellous skill, though his composition be perfect, though his detail be faultless, if his conception is trivial and his thought upon it slight, then his technical excellences betray him the more and his work is a mere virtuosity, empty and meaningless.

The outward form given to an inward vision depends upon composition. Technical skill merely develops that outward form and is governed by composition which, in its character, must possess the emotional meaning of the vision and speak directly to the emotions. It has been said that the artist struggled with nature to learn the laws of composition, and after that he devised rules for it. One should know, then, the fundamental natural law so that he may, at need, disregard the rules.

The meaning of emotional character of form in composition may be illustrated by referring directly to human experience. Mankind has looked with awe upon the mountains for countless generations. The effort to cross them taxes his utmost powers and has cost much in pain and death. The vast pyramidal forms of mountains stand in his imagination as a sign of majesty. In composition the pyramidal form is used sparingly, only when the emotion of majesty, of grandeur, is to be conveyed. Man has long looked upon tall trees with respect and has endowed them with personalities; he has bowed low before temples stately with tall columns. Tall lines in composition are used to express dignity. The sombre greys of storm clouds, full of thunder, have terrified us since the infancy of the race. Cloud forms, subtly introduced into a composition, suggest impending evil. Primal man was probably colour-blind; he learned to see colour slowly. Perhaps he recognized red first, his own blood, seen in pain in the midst of fierce passions of rage and fear. Feeling this to be true, would it not seem strangely out of harmony to paint a sweet and motherly woman in a scarlet gown?

If the illustrator has not parallel experience with the writer he cannot march beside him, but must follow, presenting inconsequential, quasi-photographic, external repetitions—a faint accompaniment, indeed—of what the author has written. The illustrator must be a person of wide knowledge, that he may have understanding; of wide sympathy, that he may know the people whom he is to picture; of creative imagination that the story may be real in his vision. To maintain such an ideal in the face of the difficulties which confront him is almost impossible, and necessitates a rare devotion to his work.

A magazine has been defined as a medium for the distribution of story and picture. It is sold at a trifling price. The publication of it at this trifling price involves a vast organization having contact with innumerable interests and bound by contracts written and implied. It *must* appear on the day when it is due to appear, otherwise these contracts are broken. Some contracts are with advertisers. Were it not for the advertisements carried in its pages the single number, to the single subscriber, would cost a hundred times or more the amount he now must pay. It is the money paid by the advertiser which makes it possible for the person of small means to have the work of the ablest writers and artists presented to him every month or week. To combine the labour of so many brains and hands that this punctuality may be maintained occupies most of the waking consciousness of publisher, editor, writer and artist. There is no eight-hour day for them.

In the necessity for such punctuality lies the exhausting handicap for the illustrator. Difficult situations must be met. Fair play sometimes forbids him from exercising his right to decline work in which he is not deeply interested. This has been called "commercializing" art, but it is not; it is complying with a need. In the lives of the old masters there were parallel instances. To return to the incident of the Sistine chapel, Michelangelo, who painted the decorations for it, was commanded by the whim of a powerful old man, and he was obliged to obey. The illustrator of

to-day is commanded by a necessity involving countless individuals over the whole country. To obey such demands requires knowledge so completely in mind that it can be set forth at once—either that or evasion. To be obliged to work far into the night, day after day, is no unusual experience. "Overtime" is a word unknown to the illustrator, the writer, the editor. Few of them can be bribed by money to the exhausting work which their love of it, for its own sake, makes them gladly do.

The illustrator's first obligation to himself and to his public is a complete understanding of the story for which he is to make illustrations. One reading of it is rarely enough. If there are any allusions to things he does not know, he must learn them. Often such allusions, if understood, suggest an entirely new conception of the story. Material inaccuracies are of slight importance. The spirit and the meaning of the story are the important things. What the author thinks about it does not matter to the artist, nor does it matter what the editor and the public think about it. What the artist himself thinks about it is all-important to him and to the public. To depict that is his reason for being. (See also DRAWING; PEN DRAWINGS; PAINTING; ART TEACHING.)

ILLUSTRES, the Latin name given to the highest magistrates of the later Roman empire. The designation was at first informal, and not strictly differentiated from other marks of honour. From the time of Valentinian I. it became an official title of the consuls, the chief praefecti or ministers, and of the commanders-in-chief of the army. Its usage was eventually extended to lower grades of the imperial service, and to pensionaries from the order of the *spectabiles*. The Illustres were privileged to be tried in criminal cases by none but the emperor or his deputy, and to delegate procuratores to represent them in the courts.

See T. Hodgkin, *Italy and her Invaders* (1892), i. 603-617; and O. Hirschfeld in *Sitzungsberichte der Berliner Akademie* (1901).

ILLYRIA, part of the Balkan Peninsula extending along the eastern shore of the Adriatic from Fiume to Durazzo, and inland as far as the Danube and the Serbian Morava. It comprises modern Dalmatia, Bosnia and Hercegovina, and Montenegro, with the southern half of Croatia-Slavonia, part of western Serbia, the sanjak of Novibazar, and the extreme north of Albania. Its landward boundaries were never clearly defined. The name was an ethnological rather than a geographical term; the older Greek historians usually wrote of "the Illyrians" (οἱ Ἰλλυριοί), while the names Illyris (Ἰλλυρίς) or less commonly Illyria (Ἰλλυρία) were subsequently used of the indeterminate area inhabited by the Illyrian tribes, i.e., a region extending eastward from the Adriatic between Liburnia on the north and Epirus on the south. The Latin name Illyricum was not synonymous with Illyria; it was a political name applied to various divisions of the Roman empire, the boundaries of which were frequently changed and often included an area far larger than Illyria properly so called.

Ethnology.—Herodotus and other Greek historians represent the Illyrians as a barbarous people, who resembled the ruder tribes of Thrace. Both are described as tattooing their persons and offering human sacrifices to their gods. The women of Illyria seem to have occupied a high position socially and even to have

exercised political power. Queens are mentioned among their rulers. Fuller and more trustworthy information can be obtained from archaeological evidence. In Bosnia the lake-dwellings at Butmir, the cemeteries of Jezerine and Glasinac and other sites have yielded stone and horn implements, iron and bronze ornaments, weapons, etc., and objects of more recent date fashioned in silver, tin, amber and even glass. These illustrate various stages in the development of primitive Illyrian civilization, from the neolithic age onward. The Hallstatt and La Tène cultures are especially well represented. Similar discoveries have been made in Dalmatia, as among the tumuli on the Sabbioncello promontory, and in Croatia-Slavonia. In Dalmatia there appears to have been a large Celtic element, and Celtic place-names are common. The ancient Illyrian languages fall into two groups, the northern, closely connected with Venetic, and the southern, perhaps allied to Messapian and now probably represented by Albanian. (See ALBANIA.)

History.—Greek colonization on the Illyrian seaboard probably began late in the 7th century B.C. or early in the 6th century. The most important settlements were Epidamnus (Durazzo) and Salona (near Spalato). Researches at Salona (see SPALATO) have brought to light Greek inscriptions, Greek pottery, etc., dating from 600 B.C. But Greek influence seems never to have penetrated far into the interior, and even on the coast it was rapidly superseded by Latin civilization after the 3rd century B.C. Until then the Illyrian tribes appear to have lived in a state of intermittent warfare with their neighbours and one another. They are said by Herodotus (ix. 43) to have attacked the temple of Delphi. Brasidas with his small army of Spartans was assaulted by them on his march (424 B.C.) across Thessaly and Macedonia to attack the Athenian colonies in Thrace. The earlier history of the Macedonian kings is one constant struggle against the Illyrian tribes. The migrations of the Celts at the beginning of the 4th century disturbed the country between the Danube and the Adriatic. The necessities of defence seem to have united the Illyrians under a chief Bardylis (about 383 B.C.) and his son Clitus, but the great Philip crushed the Illyrians completely, and annexed part of their country. During the next century we hear of them as pirates. Issuing from the secluded harbours of the coast, they ravaged the shores of Italy and Greece, and preyed on the commerce of the Adriatic. The Greeks applied to Rome for help. Teuta, the Illyrian queen, rejected the Roman demands for redress, and murdered the ambassadors; but the two Illyrian wars (229 and 219 B.C.) ended in the submission of the Illyrians, a considerable part of their territory being annexed by the conquerors. Illyria, however, remained a powerful kingdom with its capital of Scodra (Scutari in Albania), until 180 B.C., when the Dalmatians declared themselves independent. In 168 the Romans conquered and annexed the country. Dalmatia was invaded by a Roman army under Gaius Marcius Figulus in 156, but Figulus was driven back to the Roman frontier, and in Dalmatia the Illyrians were not finally subdued until 165 years afterwards. In 119 L. Caecilius Metellus overran the country and received a triumph and the surname *Dalmaticus*. But in 51 a Dalmatian raid on Liburnia led to a renewal of hostilities; the Roman armies were often worsted, and though in 39 Asinius Pollio gained some successes it was not until Octavian took the field in person that the Dalmatians submitted in 33. They again revolted in 16 and 11, and in A.D. 6–9 joined the rebel Pannonians. In A.D. 9, however, Tiberius entirely subjugated them, and Dalmatia, Iapydia and Liburnia were united as the province of Illyricum.

Latin civilization spread rapidly, the cultivation of the vine was introduced, gold-mining was carried on in Bosnia, and commercial cities arose along the coast. Illyria became one of the best recruiting grounds for the Roman legions; and in troubled times Illyrian soldiers fought their way up from the ranks to the imperial purple. Claudius, Aurelian, Probus, Diocletian and Maximian were all sons of Illyrian peasants. The importance of Illyricum caused its name to be extended to many neighbouring districts; in the 2nd century A.D. *Illyricus Limes* included Noricum, Pannonia, Moesia, Dacia and Thrace. The Via Egnatia, the great line of road which connected Rome with Constantinople and the East,

led across Illyricum from Dyrrachium to Thessalonica. Either Diocletian or Constantine made Illyricum one of the four prefectures, each governed by a *praefectus praetorio*, into which the empire was divided. This prefecture included Pannonia, Noricum, Crete and the entire Balkan peninsula except Thrace, which was attached by Constantine to the prefecture of the East. From the partition of the empire in 285 until 379 Illyricum was included in the western empire, but thenceforward eastern Illyricum was annexed to the eastern empire; its frontier was almost identical with the line of demarcation between Latin-speaking and Greek-speaking peoples, and roughly corresponded to the boundary which now severs Latin from Greek Christianity in the Balkan peninsula.

In 441 and 447 the country was ravaged by the Huns. In 481 Dalmatia was added to the Ostrogothic kingdom, which already included the more northerly parts of Illyricum. Bands of Slavonic invaders gradually established themselves in Illyria, where, unlike the earlier barbarian conquerors, they formed permanent settlements. Between 600 and 650 the main body of the immigrants (Croats and Serbs) occupied Illyria (see SERBIA: History; and SLAVS). The Croats settled in the western half of Illyria, the Serbs in the eastern; thus the former came under the influence of Italy and Roman Catholicism, the latter under the influence of Byzantium and the Greek Church. Hence the distinction between them became a marked difference of civilization and creed, which has always tended to keep the Illyrian Slavs politically disunited.

The Croats and Serbs rapidly absorbed most of the Latinized Illyrians. But the wealthy and powerful city-states on the coast were strong enough to maintain their independence and their distinctively Italian character. Other Roman provincials took refuge in the mountains of the interior; some Illyrian tribes remained unconquered among the mountains of Albania and were never Slavonized. With these exceptions Illyria became entirely Serbo-Croatian in population, language and culture. The name of Illyria disappeared from history, but was revived in the "Illyrian Provinces" of 1809 and the "Kingdom of Illyria" of 1816–49. For the political propaganda known as Illyrism, see CROATIA-SLAVONIA: History.

ILMENAU, a town and summer resort of Germany, in the republic of Thuringia, at the north of the Thuringian Forest, on the river Ilm, 30 m. by rail south of Erfurt. Pop. (1925) 13,905. Formerly a part of the county of Henneberg, Ilmenau came in 1631 into the possession of electoral Saxony, afterwards passing to Saxe-Weimar. It was a favourite resort of Goethe, who wrote here his *Iphigenie*. It manufactures glass, porcelain, toys, chemicals, surgical instruments and turnery.

ILMENITE or **TITANIC IRON-ORE**, an iron-black mineral resembling haematite in form and habit and formerly regarded as a titaniferous haematite (FeTi)₂O₃. It is now considered to be an iron titanate, FeTiO₃, isomorphous with *pyrophanite* (MnTiO₃) and *geikielite*, MgTiO₃. The composition indicated by the formula is FeO=47.4 and TiO₂=52.6%; but analyses show wide variations due to the presence of an excess of ferric oxide and, in some varieties, magnesia. Ilmenite crystallizes in the hexagonal system with rhombohedral symmetry. Well-formed crystals are rare. The mineral is distinguished from haematite by its black streak and slight magnetism. It is, however, not polar, like magnetite. Hardness, 5. Sp. G., 4.8. Colour, black. Lustre, sub-metallic. Opaque. The name is derived from the Ilmen mountains in the southern Urals.

Ilmenite occurs in association with magnetite in gneisses and schists, often in beds of considerable size, but of little economic value. It is a frequent constituent of the more basic igneous rocks, as magnetite is of the more acid types. Some of the black sands

derived from these rocks consist largely of grains of ilmenite. For *titano-magnetite* see under MAGNETITE. (F. H. HA.)

ILOILO, a municipality (with administration centre and 16 *barrios* or districts), the most important port of the western Bisayan group and the principal sugar port of the archipelago, capital of the province of Iloilo, Panay, Philippine Islands, about 258 m. from Manila. It is a terminal of the Panay railway which runs to Capiz. Pop. (1918) 49,114, of whom 24,898 were males and 382 white, including a considerable percentage of Basques. Iloilo boasts an intelligent, wealthy and cultured mestizo population. It is built on low, sandy ground and is irregularly laid out. In Iloilo (or nearby) are several private and religious schools, as well as a public high school and other public schools. The harbour is well protected by the island of Guimaras which lies opposite Iloilo, and ocean-going vessels can lie in the channel. The surrounding country, which has excellent motor roads leading in various directions, is fertile and well cultivated, producing sugar, tobacco and rice in abundance. It is the fourth centre in point of population in the Philippines, and is the great commercial rival of Cebu. Various hardwoods grow nearby. Coco-nut oil, lime, vinegar and various articles made from palmwood are among the manufactures. In 1918, it had 67 manufacturing establishments, with output valued at 2,463,000 pesos; and 1,295 household industry establishments with output valued at 364,900 pesos; as well as three rice-mills with output valued at 902,800 pesos. A meteorological station is established here. Of the 30 schools, 17 were public. The language is a dialect of Bisayan. Much of Iloilo was burned by the Filipino insurgents soon after its capture by the troops of the United States in Feb. 1899.

ILSENBURG, a village and health resort of Germany, in Prussian Saxony, situated under the north foot of the Harz mountains, at the entrance to the Ilsethal, 6 m. N.W. from Wernigerode by the railway to Goslar. Pop. (1925) 5,224. It manufactures metal wares.

The old castle, Schloss Ilsenburg, lying on a high crag above the town, was originally an imperial stronghold probably built by the German king Henry I.

IMAGE, SELWYN (1849–), English illustrator and designer, was born at Bodiam, Sussex. He was educated at Marlborough, and New College, Oxford, and received his art training at the Slade school, Oxford, under Ruskin. In 1872 he was ordained deacon and in 1878 priest, having been a curate at All Hallows, Tottenham, in 1875 and at St. Anne's Soho, from 1876 to 1880. In 1900 he became master of the Art Workers' guild and from 1916 he was Slade professor at Oxford. Among his published lectures are: *Art, Morals and the War* (1914) and a treatise on preparing cartoons for stained glass and *grisaille* work, which is included in Gleeson White's *Practical Designing* (1894). He designed the west window of St. Luke's church, Camberwell, and the Four Archangels in Morthoe church, Devon. His *Poems and Carols* were published in 1894.

IMAGE, in general, a copy, representation, exact counterpart of something else. Thus the reflection of a person in a mirror is called an image. For the worship of images see IDOLATRY and ICONOCLASTS.

IMAGE WORSHIP: see IDOLATRY.

IMAGINARY NUMBER: see COMPLEX NUMBER.

IMAGINATION, in general, the power or process of producing mental pictures or ideas. The term is technically used in psychology for the process of reviving in the mind percepts of objects formerly given in sense perception. Since this use of the term conflicts with that of ordinary language, some psychologists have preferred to describe this process as "imaging" or "imagery" or to speak of it as "reproductive" as opposed to "productive" or "constructive" imagination (see PSYCHOLOGY).

IMAGO, a term used of the sexually mature stage of an insect (*q.v.*), in contradistinction to its immature or larval stages.

IMĀM (Arabic, "leader" in the sense of a "pattern whose example is followed"). In the Qur'ān it is used several times of leaders and (ii. 118) of Abraham, "Lo, I make thee a pattern for mankind." *Imām* thus became the name of the head of the Muslim community. His duty is to be the lieutenant, the Caliph (*q.v.*) of

the Prophet, to guard the faith and maintain the government of the state. Round the origin and basis of his office all controversies as to the Muslim state centre. The Sunnites hold that it is for men to appoint; the Shī'ites in general, that the appointment lies with God, through the Prophet or otherwise, and that He always has appointed. The Khārijites recognize no absolute need of an Imām; he is convenient and allowable. Another distinction between the Sunnites and the Shī'ites is that the Sunnites regard the Imām as liable to err, and to be obeyed even though he personally sins, provided he maintains the ordinances of Islām. But the Shī'ites believe that the divinely appointed Imām is also divinely illumined and preserved (*ma'sūm*) from sin. The above is called the greater Imāmate. The lesser Imāmate is the leadership in the Friday prayers. This was originally performed by the Imām in the first sense, who not only led in prayers but delivered a sermon (*khutba*); but with the growth of the Muslim empire and the retirement of the caliph from public life, it was necessarily given over to deputies, who in Turkey were servants of the state, each in charge of his own parish; they performed the rites of circumcision, marriage and burial. In Persia among Shī'ites their position is more purely spiritual, and they are independent of the state. A few of their leaders are called *Mujtahids*, i.e. capable of giving an independent opinion on questions of religion and canon law. A third use of the term Imām is as an honorary title. It is thus applied to leading theologians, e.g. to Abū Ḥanīfa, ash-Shāfi'ī, Malik ibn Anas, Aḥmad ibn Ḥanbal (these are called "the four Imāms"), Ghazālī.

BIBLIOGRAPHY.—McG. de Slane's transl. of Ibn Khaldūn's *Prolegomenes*, i. 384 seq., 402 seq., 426 seq., 445; iii. 35, 58 seq. (1851); Haarbriicker's transl. of Shahrastāni by index; 56 seq.; T. W. Arnold, *The Caliphate* (1926), by index; Macdonald's *Development of Muslim Theology* (1903). (D. B. M.)

IMBECILE, weak or feeble, particularly in mind. The term "imbecility" is used conventionally of a condition of mental degeneration less profound than "idiocy" (see INSANITY).

IMBREX, in architecture, one of the raised, covering tiles, placed over the joints between the flat or pan tiles in an ancient Greek or Roman roof. The pan tiles were laid with the joints in each course, or row, exactly in line with the joints above and below, so that the imbrex tiles formed continuous ridges. In the simpler types, the imbrex was approximately semi-circular, but in more monumental examples, especially where the roof tiles were in marble, the imbrex had straight sides and an angular top. At the lower end of each row of imbrex tiles was an ante-fix (*q.v.*) or decorative terminal.

IMBROS, an island in the Aegean belonging to Turkey, at the southern end of the Thracian Chersonese peninsula. Herodotus (v. 26) mentions it as an abode of the historic Pelasgians (*q.v.*). It was, like Samothrace, a seat of the worship of the Cabeiri (*q.v.*). There is much volcanic rock and parts of the island are very fertile. Wheat, oats, barley, olives and fruit are grown. The island was occupied by Greece during and after the World War. It was also an important base for the British and Allied operations in the Eastern Mediterranean at the same time. It was returned to Turkey by the Treaty of Lausanne (1923). Its population is about 9,000.

IMHOTEP, a famous physician and sage of ancient Egypt, who afterwards became the god of medicine.

Egyptian texts speak of Imhotep as a minister who lived in the reign of the Pharaoh Zoser of the third dynasty (c. 2980 B.C.). He acquired a great reputation for his wisdom and learning and became, first a demi-god, and, under the Ptolemies, the Egyptian god of medicine. By the Greeks Imhotep was called Imouthes, and by them was identified with Asklepios, the god of healing. Although certain Egyptologists have regarded Imhotep as legendary, and have doubted that he lived as an actual man in the reign of Zoser, recent discoveries have converted into certainty what was ever a probability. There can no longer be the slightest doubt that Imhotep is a historical personage, and that in common with other Egyptian nobles, he held civil as well as religious offices. He was vizier, architect, chief ritualist, sage and scribe under the powerful king who built the celebrated "step pyramid" of Sakkara. There is no contemporary evidence that Imhotep

was a physician, but his priestly duties were intimately concerned with magic, and in Egypt magic and medicine were inseparably related. Imhotep is referred to in certain literary texts as a sage of great renown, and he was born in the neighbourhood of Memphis, his parents being Kanufer and Khreduonkh. Under the Ptolemaic dynasties he was invested with all the attributes of deity and was regarded as the son of the Memphite god Ptah, whose name is substituted for that of his earthly father Kanufer. Imhotep had shrines as well as temples of his own in various parts of Egypt and of Nubia. It was believed that miraculous cures could be effected by his divine intervention, and his temples were thronged with sufferers many of whom have left records of their gratitude. Statues and figurines of Imhotep as god of medicine have been found in considerable numbers, and these attest his widespread popularity. The evidence afforded by Egyptian and Greek texts supports the view that Imhotep's reputation was respected in very early times, and that he became at least a demigod not long after his death. His prestige increased with the lapse of centuries, and his temples in Greek times were the centres of medical teaching. His posthumous deification is paralleled by that of another Egyptian sage, Amenophis the son of Hapu, who lived in the eighteenth dynasty and held civil and religious offices in the reign of Amenophis III., and was deified under the Ptolemies and closely associated with Imhotep and with medicine. (See W. R. Dawson, "Amenophis the son of Hapu," *Aegyptus*, vol. vii., pp. 113-138, 1926.) Imhotep and Amenophis as deified mortals stand almost alone in Egyptian history, and both, during their lives, must have been men of outstanding merit to have earned such signal posthumous recognition.

IMIDAZOLES AND IMINAZOLES: see GLYOXALINES.

IMITATION, reproduction or repetition of an action or thought as observed in another person or in oneself, or the construction of one object in the likeness of another. By some writers (e.g., Preyer and Lloyd Morgan) the term "imitation" is limited to cases in which one person copies the action or thought of another; others have preferred a wider use of the term (i.e., including "self-imitation"), and have attempted to classify imitative action into various groupings, e.g., as cases of "conscious imitation," "imitative suggestion," "plastic imitation" (as when the members of a crowd subconsciously reproduce one another's modes of thought and action), and the like. The main distinction is that which takes into account the question of attention (*q.v.*). In *conscious* imitation, the attention is fixed on the act and its reproduction; in *unconscious* imitation the reproduction is entirely mechanical and the agent does not "attend" to the action or thought which he is copying; in *subconscious* imitation the action is not deliberate, though the necessary train of thought would immediately follow if the attention were turned upon it under normal conditions. Imitation plays an extremely important part in human and animal development, and a clear understanding of its character is important both for the study of primitive peoples, and also in the theories of education, art and sociology. The child's early development is in large measure imitative; thus the first articulate sounds and the first movements are mainly reproductions of the words and actions of parents, and even in the later stages that teacher is likely to achieve the best results who himself gives examples of how a word should be pronounced or an action done. The impulse to imitate is, however, not confined to children; there is among the majority of adults a tendency to assimilate themselves either to their society or to those whom they especially admire or respect; this tendency to shun the eccentric is rooted deeply in human psychology. Moreover, even among highly developed persons the imitative impulse frequently overrides the reason, as when an audience, a crowd, or even practically a whole community is carried away by a panic for which no adequate ground has been given, or when a cough or a yawn is imitated by a company of people. Such cases may be compared with those of persons in mesmeric trances who mechanically copy a series of

movements made by the mesmerist. The universality of the imitative impulse has led many psychologists to regard it as an instinct (so William James, *Principles of Psychology*, ii. 408; cf. *INSTINCT*), and in that large class of imitative actions which have no obvious ulterior purpose the impulse certainly appears to be instinctive in character. On the other hand where the imitator recognizes the particular effect of a process and imitates with the deliberate intention of producing the same effect, his action can scarcely be classed as instinctive. A considerable number of psychologists have distinguished imitative from instinctive actions (e.g., Baldwin, and Sully). According to Darwin the imitative impulse begins in infants at the age of four months. It is to be noted, however, that the child imitates, not every action indiscriminately, but especially those towards which it has a congenital tendency. The same is true of animals; though different kinds of animals may live in close proximity, the young of each kind imitate primarily the actions of their own parents.

Among primitive men imitation plays a very important part. The savage believes that he can bring about events by imitating them. He makes, for instance, an image of his enemy and pierces it with darts or burns it, believing that by so doing he will cause his enemy's death; similarly sailors would whistle, or farmers would pour water on the ground, in the hope of producing wind or rain. This form of imitation is known as sympathetic magic (see *MAGIC*). The sociological importance of imitation is elaborately investigated by Gabriel Tarde (*Les Lois de l'imitation*, 2nd ed., 1895), who bases all social evolution on the imitative impulse. He distinguishes "custom imitations," i.e., imitations of ancient or even forgotten actions, and "mode imitations," i.e., imitations of current fashions. New discoveries are, in his scheme, the product of the conflict of imitations. This theory, though of great value, seems to neglect original natural similarities which, by the law of causation, produce similar consequences, where imitation is geographically or chronologically impossible.

The term "imitation" has also the following special uses:—

1. *In Art-theory.*—According to Plato all artistic production is a form of imitation (*μίμησις*). That which really exists is the idea or type created by God; of this type all concrete objects are representations, while the painter, the tragedian, the musician are merely imitators, thrice removed from the truth (*Rep.* x. 596 *seq.*). Such persons are represented by Plato as a menace to the moral fibre of the community (*Rep.* iii.), as performing no useful function, drawing men away from reality and pandering to the irrational side of the soul. All art should aim at moral improvement. Plato clearly intends by "imitation" more than is connoted by the modern word; though in general he associates with it all that is bad and second-rate, he in some passages admits the value of the imitation of that which is good, and thus assigns to it a certain symbolic significance. Aristotle, likewise regarding art as imitation, emphasizes its purely artistic value as purging the emotions (*κάθαρσις*), and producing beautiful things as such (see *AESTHETICS*, *CATHARSIS* and *FINE ARTS*).

2. *In Biology*, the term is sometimes applied to the assimilation by one species of certain external characteristics (especially colour) which enable them to escape the notice of other species which would otherwise prey upon them. It is a form of protective resemblance and is generally known as mimicry (*q.v.*; see also *COLOURS OF ANIMALS*).

3. *In Music*, the term "imitation" is applied in contrapuntal composition to the repetition of a passage in one or more of the other voices or parts of a composition. When the repetition is note for note with all the intervals the same, the imitation is called "strict" and becomes a canon (*q.v.*); if not it is called "free," the latter being much the more common. There are many varieties of imitation, known as imitation "by inversion," "by inversion and reversion," "by augmentation," "by diminution" (see *Grove's Dictionary of Music*, s.v., and text-books of musical theory).

IMITATION OF CHRIST, THE (*Imitatio Christi*), the title of a famous mediaeval Christian devotional work, much used still by both Catholics and Protestants and usually ascribed to Thomas à Kempis. The prolonged controversy over the author-

ship of the work has at the present time been narrowed down to the issue, "either Thomas à Kempis, or an unknown author."

The following is a statement of the facts that may be received as certain:—

1. It is the verdict of the most competent modern expert opinion that there is no palaeographical reason for suspecting that any known ms. of the *Imitation* (or any part of it) is earlier than the first quarter of the 15th century. The earliest dated ms. is of Bk. I. only (1424).

2. A Latin letter of a Dutch canon regular, named Johann van Schoonhoven, exhibits such a close connection with Bk. I. that plagiarism on the one side or the other is the only possible explanation. It is capable of demonstration that the author of the *Imitation* was the borrower, and that the opposite hypothesis is inadmissible. Now, this letter can be shown to have been written after 1382. Therefore Bk. I. was beyond controversy written between the years 1382 and 1424.

3. It is not here assumed that the four parts of the work formed a single work, or even that they are all by the same author; and the date of the other three books cannot be fixed with the same certainty. But, on the one hand, before the beginning of the 15th century there is no trace whatever of their existence—a strong argument that they did not yet exist; and on the other hand, after 1424 nearly each year produces its quota of mss. and other signs of the existence of these books become frequent. Moreover, as a matter of fact, the four treatises did commonly circulate together. The presumption is strong that Bks. II., III., IV., like Bk. I., were composed shortly before they were put into circulation.

It may then be taken as proved that the *Imitation* was composed between 1380 and 1425, and probably towards the end rather than the beginning of that period. Having ascertained the date, we must consider the birthplace.

4. A number of idioms and turns of expression throughout the book show that its author belonged to some branch of the Teutonic race.

5. Of the 400 mss. of the *Imitation* 340 come from the Teutonic countries—another argument in favour of its Teutonic origin. Again, 100 of them, including the earliest, come from the Netherlands. This number is quite disproportionate to the relative size of the Netherlands, and so points to Holland as the country in which the *Imitation* was first most widely circulated and presumably composed.

6. There is a considerable body of early evidence, traceable before 1450, that the author was a canon regular.

7. Several of the mss. were written in houses belonging to the Windesheim Congregation of canons regular, or in close touch with it. Moreover, there is a specially intimate literary and spiritual relationship between the *Imitation* and writings that emanated from what has been called the "Windesheim Circle."

8. There can be no question that in the Windesheim Congregation itself there was already, during Thomas à Kempis's lifetime, a fixed tradition that he was the author of the *Imitation*. The most important witness to this tradition is Johann Busch, who passed a great part of his life in Windesheim, only a few miles from Mount St. Agnes, the monastery of which Thomas was an inmate. It would be hard to find a more authentic witness. Another witness is Hermann Rhyd, a German member of the Windesheim Congregation, who also had personally known Thomas. Moreover, the tradition existed in Thomas à Kempis's own monastery shortly after his death; for John Mauburne became a canon in Mount St. Agnes within a few years of Thomas's death, and he states more than once that Thomas wrote the *Imitation*.

9. The earliest biographer of Thomas à Kempis was an anonymous contemporary: the *Life* was printed in 1494, but it exists in a ms. of 1488. The biographer says he got his information from the brethren at Mount St. Agnes, and he states in passing that Bk. III. was written by Thomas. Moreover, he appends a list of Thomas's writings, 38 in number, and 5-8 are the four books of the *Imitation*.

Internal arguments have been urged against Thomas's author-

ship. It has been said that his certainly authentic writings are so inferior that the *Imitation* could not have been written by the same author. It may be granted that Thomas was a prolific writer, that his writings vary very much in quality and that the *Imitation* surpasses all the rest, and that some are on a level very far below it; still, when at their best, some of the other works are not unworthy of the author of the *Imitation*.

It has been said that the *Imitation of Christ* has had a wider religious influence than any book except the Bible, and if the statement be limited to Christendom, it is probably true. The *Imitation* has been translated into over fifty languages, and is said to have run through more than 6,000 editions. The other statement, often made, that it sums up all that is best of earlier Western mysticism—that in it "was gathered and concentrated all that was elevating, passionate, profoundly pious in all the older mystics" (Milman) is an exaggeration. It depreciates unduly the elder mystics and fails to do justice to the originality of the *Imitation*. For its spiritual teaching is different from the mysticism of Augustine in the *Confessions*, or of Bernard in the *Sermons on the Song of Songs*; from the scholastic mysticism of the St. Victorians or Bonaventura; and from the mysticism of the German school of Eckhart, Suso, Tauler and Ruysbroek. Again, it is different from the later school of St. Teresa and St. John of the Cross, and from the introspective methods of what may be called the modern school of spirituality. The *Imitation* stands apart, unique, as the principal and most representative utterance of a special phase of religious thought—non-scholastic, non-platonic, positive and merely religious in its scope—herein reflecting faithfully the spirit of the movement initiated by Gerhard Groot (*q.v.*), and carried forward by the circles in which Thomas à Kempis lived. In contrast with many mystical writings it is of limpid clearness, every sentence being easily understandable by all whose spiritual sense is in any degree awakened. No doubt it owes its universal power to this simplicity, to its freedom from intellectualism and its direct appeal to the religious sense and to the extraordinary religious genius of its author.

BIBLIOGRAPHY.—The best account in English of the Controversy is that given by F. R. Cruise in his *Thomas à Kempis* (1887). Works produced before 1880 are in general, with the exception of those of Eusebius Amort, superannuated, and deal in large measure with points no longer of any living interest. A pamphlet by Cruise, *Who was the Author of the Imitation?* (1898) contains sufficient information on the subject for all ordinary needs; it has been translated into French and German, and may be regarded as the standard handbook.

The best Latin edition of the *Imitation* is that of Hirsche (1874), which follows closely the autograph of 1441 and reproduces the rhythmical character of the book. Of English translations the most interesting is that by John Wesley, under the title *The Christian's Pattern* (1735). (E. C. B.; X.)

IMITATION RUBBER: see RUBBER: Synthetic.

IMMACULATE CONCEPTION, THE. This dogma of the Roman Catholic Church was defined as "of faith" by Pope Pius IX. in the Bull *Ineffabilis Deus* (Dec. 8, 1854) in the following terms: "The doctrine which holds that the Blessed Virgin Mary, from the first instant of her conception, was, by a most singular grace and privilege of Almighty God, in view of the merits of Jesus Christ, the Redeemer of the human race, preserved from all stain of Original Sin, is a doctrine revealed by God, and therefore to be firmly and steadfastly believed by all the faithful." These words presuppose the distinction between original, or racial, and actual, or personally incurred sin. There is no dispute that the Church has always held the Blessed Virgin to be sinless, in the sense of actual or personal sin. The question of the Immaculate Conception regards original or racial sin only. It is admitted that the doctrine as defined by Pius IX. was not explicitly mooted before the 12th century. But it is claimed that it is implicitly contained in the teaching of the Fathers. Their expressions on the subject of the sinlessness of Mary are, it is pointed out, so ample and so absolute that they must be taken to include original sin as well as actual. Controversy on the subject was forbidden by the Council of Trent, pending further action on the part of the Holy See; but the doctrine was widely taught in the Roman Catholic Church long before the middle of the 19th century when bishops of various countries began to press for a definition. Pius IX. ap-

pointed commissions to investigate the subject, and was advised that the doctrine was one which could be defined and that the time for definition was opportune. On Dec. 8, 1854, in a great assembly of bishops at St. Peter's, Rome, he promulgated the Bull *Ineffabilis Deus*, in which the history of the doctrine is summarily traced, and which contains the definition given above.

The chief répertoire of Patristic passages, both on the doctrine and on the festival, is C. Passaglia's great collection, entitled *De immaculato Deiparae semper Virginis conceptu commentarius* (3 vols., Rome, 1854-55). The state of Catholic belief in the middle of the 19th century is well brought out in *La Croyance générale et constante de l'Eglise touchant l'immaculée conception de la bienheureuse Vierge Marie*, published in 1855 by T. M. J. Gousset (1792-1866). For English readers the doctrine, and the history of its definition, is clearly stated by Archbishop Ullathorne in *The Immaculate Conception of the Mother of God* (2nd ed., London, 1904), and with many references, by F. C. Holweck, art. "Immaculate Conception" in the *Catholic Encyclopaedia*, and (from a different point of view) in the article, "Immaculate Conception" in Hastings' *Encyclopaedia of Religion and Ethics*.

IMMANENCE, in philosophy and theology a term applied, in contradistinction to "transcendence," to the fact or condition of being entirely within something (from Lat. *in-manere*, to dwell in, remain). Its most important use is for the theological conception of God as existing in and throughout the created world, as opposed, for example, to Deism (*q.v.*), which conceives Him as separate from and above the universe. This conception has been expressed in a great variety of forms (see **THEISM**, **PANTHEISM**).

IMMANUEL BEN SOLOMON (c. 1265-c. 1330), Hebrew poet, was born in Rome. He was a contemporary and friend of Dante, and his verse shows the influence of the "divine poet." Immanuel's fame chiefly rests on his poems, especially the collection (in the manner of Harizi, *q.v.*) entitled *Mehabberoth*, a series of 27 good-natured satires on Jewish life. Most popular is an additional section numbered 28 (often printed by itself) called *Hell and Paradise* (*ha-Tophet v'ha-Eden*).

See J. Chotzner, *Hebrew Humour* (1905), pp. 82-102.

IMMERMANN, KARL LEBERECHE (1796-1840), German dramatist and novelist, was born on April 24, 1796 at Magdeburg, the son of a government official. His legal studies at Halle were interrupted by the call to arms and by the campaign of 1815, after which he returned to the university. He was *Referendar* in Magdeburg, and in 1819 *Assessor* at Münster in Westphalia. Here he made the acquaintance of Elise von Lützow, Countess von Ahlefeldt, wife of the leader of the famous "free corps" (see Lützow), and their relationship is reflected in several dramas written about this time. In 1823 Immermann was appointed judge at Magdeburg, and in 1827 was transferred to Düsseldorf as *Landgerichtsrat* or district judge. Thither the countess, whose marriage had in the meantime been dissolved, followed him, and, though refusing his hand, shared his home until his marriage in 1839. In 1834 Immermann became manager of the Düsseldorf theatre where he accomplished great things in spite of lack of adequate funds. In 1836 he returned to his official duties. He died at Düsseldorf on Aug. 25, 1840.

Immermann's early plays are imitations, partly of Kotzebue's, partly of the Romantic dramas of Tieck and Müllner, and are now forgotten. In 1826, however, appeared *Cardenio und Celinde*, a love tragedy ridiculed by Platen in his wittiest satire, *Der romantische Oedipus*. Between 1827 and 1832 Immermann wrote a series of historical tragedies, *Das Trauerspiel in Tirol* (1827), *Kaiser Friedrich II.* (1828) and a trilogy from Russian history, *Alexis* (1832). His masterpiece is the poetic mystery, *Merlin* (1831), which, like its model, *Faust*, deals with the problems of spiritual life. Immermann's important dramaturgic experiments in Düsseldorf are described in detail in *Düsseldorfer Anfänge* (1840). As a novelist he clearly stands on the boundary line between Romanticism and modern literature; his *Epigonen* (1836) might be described as one of the last Romantic imitations of Goethe's *Wilhelm Meister*, while the satirical picture of contemporary life in his second novel, *Münchhausen* (1838), forms a full break with the older literature. In *Münchhausen* is embedded the admirable story of village life, *Der Oberhof*. His last work was an unfinished epic, *Tristan und Isolde* (1840).

Immermann's *Gesammelte Schriften* were published in 14 vols. in 1835-43; a new edition, with biography and introduction by R. Boxberger, in 20 vols. (Berlin, 1883); selected works, edited by M. Koch (4 vols., 1887-88) and F. Muncker (6 vols., 1897). See G. zu Putlitz, *Karl Immermann, sein Leben und seine Werke* (2 vols., 1870); F. Freiligrath, *Karl Immermann, Blätter der Erinnerung an ihn* (1842); H. Mayne, *Immermann, Der Mann und sein Werk* (Munich, 1921).

IMMERSION, the act of being plunged into a fluid, or being overwhelmed by anything; in astronomy, the disappearance of a heavenly body in the shadow of another, especially of a satellite in the shadow of its primary.

IMMIGRATION, the movement of population, other than that of casual visitors or travellers, into one country from another. See **MIGRATION**; **POPULATION**.

IMMINGHAM, seaport, Lincolnshire, England, on the south shore of the Humber estuary, 9 m. S.E. of Hull and 5 m. N.W. of Grimsby. The docks belong to the L.N.E. railway company and consist of a square basin and two long arms (including a graving dock), of a total area of 45 ac., with 5,400 ft. of quayage; and 47 to 43 ft. depth of water. This port was built (1906-12) here because the deep water channel of the Humber leads right to the dock gates and vessels can enter and leave unaided at all states of the tide. A new town, which has grown up round the docks, is connected by electric tramway and light railway with Grimsby. Pop. (1921) 2,150.

IMMOLATION, the ceremonial rites performed in the preparation of victims for sacrificial purposes. The human sacrifice or *sati* (suttee) of India consists of the immolation of a widow on the funeral pyre of her husband and the Khond sacrifice of the Meriah; the days preceding the sacrifice being devoted to increasing the sanctity of the victim by various processes of anointing and other ceremonies. See **SACRIFICE**.

IMMORTALITY, the condition or quality of being exempt from death or annihilation. The belief in human immortality in some form is almost universal; even in early animistic cults the germ of the idea is present, and in all the higher religions it is an important feature. This article is confined to summarizing the philosophical or scientific arguments for and against the doctrine of the persistence of the human soul after death. For the Christian doctrine, see **ESCHATOLOGY**; and for other religions, see the separate articles.

The opinion of Socrates is uncertain. In the *Apology* he is represented as sure that "no evil can happen to a good man, either in life or after death," but as not sure of what man's future lot will be. In the *Phaedo* a confident expectation is ascribed to him. Only his body will be buried; he will go away to the happiness of the blessed. The silence of the *Memorabilia* of Xenophon must be admitted as an argument to the contrary; but the probability seems to be that Plato in the *Phaedo* did not altogether misrepresent the master. In Plato's own thought the belief held a prominent position. "It is noteworthy," says D. G. Ritchie, "that, in the various dialogues in which Plato speaks of immortality, the arguments seem to be of different kinds, and most of them quite unconnected with one another." (*Plato* p. 146.) The estimate to be formed of his reasoning has been well stated by A. M. Fairbairn, "Plato's arguments for immortality, isolated, modernized, may be feeble, even valueless, but allowed to stand where and as he himself puts them, they have an altogether different worth. The ratiocinative parts of the *Phaedo* thrown into syllogisms may be easily demolished by a hostile logician; but in the dialogue as a whole there is a subtle spirit and cumulative force which logic can neither seize nor answer" (*Studies in the Philosophy of Religion*, p. 226 [1876]).

Aristotle held that only *voûs*, or the active intellect, in man is immortal. His views are conditioned by his psychology, body and soul being a complete whole, in which the elements are inseparably united. Soul cannot exist disembodied. Yet he makes a reservation in favour of the highest element in man: this indeed is immortal, but apparently not in an individual form. He seems not to have believed what could be called personal immortality. The Stoics were not agreed upon the question. Cleanthes is said to have held that all survive until the great conflagration which closes the cycle; Chrysippus that only the wise will do so. Marcus

Aurelius teaches that even if the spirit survives for a time it is at last "absorbed in the generative principle of the universe." Epicureanism thought that "the wise man fears not death, before which most men tremble; for, if we are, it is not; if it is, we are not." Augustine adopts a Platonic thought when he teaches that the immortality of the soul follows from its participation in the eternal truths. The Apologists themselves welcomed, and commended to others, the Christian revelation as affording a certainty of immortality such as reason could not give. The Aristotelian school in Islam did not speak with one voice upon the question; Avicenna declared the soul immortal, but Averroes assumed only the eternity of the universal intellect. Albertus Magnus argued that the soul is immortal, as *ex se ipsa causa*, and as independent of the body. Pietro Pomponazzi, like Duns Scotus, maintained that the soul's immortality could be neither proved nor disproved by reason. Spinoza, consistently with his pantheism denying personal immortality, affirms that "the human mind cannot be absolutely destroyed with the body, but there remains of it something which is eternal" (*Eth.* v. prop. xxiii). The reason he gives is that, as this something "appertains to the essence of the mind," it is "conceived by a certain eternal necessity through the very essence of God."

Leibniz, in accord with the distinctive principle of his philosophy, affirmed the absolute independence of mind and body as distinct monads, the parallelism of their functions in life being due to a pre-established harmony. For the soul, by its nature as a single monad indestructible and, therefore, immortal, death meant only the loss of the monads constituting the body, and the return of the soul to the pre-existent state. The argument of Ernst Platner (*Philos. Aphor.* i. 1174, 1178) is similar. He adds a reason that recalls one of Plato's: "As manifestly as the human soul is by means of the senses linked to the present life, so manifestly it attaches itself by reason, and the conceptions, conclusions, anticipations and efforts to which reason leads it, to God and eternity."

Against the first kind of argument, as formulated by Moses Mendelssohn, Kant advances the objection that, although we may deny the soul extensive quantity and divisibility into parts, we cannot refuse to it intensive quantity, degrees of reality; and consequently its existence may be terminated not by decomposition, but by gradual diminution of its powers. This denial of any reasonable ground for belief in immortality in the *Critique of Pure Reason* (*Transcendental Dialectic*, bk. ii. ch. i.) is, however, not his last word on the subject. In the *Critique of the Practical Reason* (*Dialectic*, ch. i. sec. iv.) the immortality of the soul is shown to be a postulate. Holiness, "the perfect accordance of the will with the moral law," demands an endless progress; and "this endless progress is only possible on the supposition of an endless duration of the existence and personality of the same rational being (which is called the immortality of the soul)." Not demonstrable as a theoretical proposition, the immortality of the soul "is an inseparable result of an unconditional *a priori* practical law." The moral interest, which is so decisive on this question in the case of Kant, dominates Bishop Butler also. A future life for him is important, because our happiness in it may depend on our present conduct; and, therefore, our action here should take into account the reward or punishment that it may bring to us hereafter. As he maintains that probability may and ought to be our guide in life, he is content with proving in the first chapter of the *Analogy* that "a future life is probable from similar changes (as death) already undergone in ourselves and in others, and from our present powers, which are likely to continue unless death destroys them . . . but there is no proof that it will, either from the nature of death," of the effect of which on our powers we are altogether ignorant, "or from the analogy of nature, which shows only that the sensible proof of our powers (not the powers themselves) may be destroyed." (Analysis of chapter I. in Angus's edition of *The Analogy*.) Butler recognizes that "reason did, as it well might, conclude that it should finally, and upon the whole, be well with the righteous and ill with the wicked," but only "revelation teaches us that the next state of things after the present is appointed

for the execution of this justice" (ch. ii. note 10). He does not use this general anticipation of future judgment, as he might have done, as a positive argument for immortality.

Adam Ferguson (*Institutes of Moral Philosophy*, p. 119, new ed., 1800), argues that the desire for immortality itself as an instinct is an indication of the Creator's intention. From the standpoint of modern science John Fiske confirms the validity of such an argument; for what he affirms in regard to belief in the divine is equally applicable to this belief in a future life. "If the relation thus established, in the morning twilight of man's existence, between the human soul and a world invisible and immaterial is a relation of which only the subjective term is real and the objective term is non-existent; then I say it is something utterly without precedent in the whole history of creation" (*Through Nature to God*, 1899, p. 188, 189). Whatever may have been Hegel's belief in regard to personal immortality, the logical issue of his absolute idealism would seem to be a rejection of the continuance of finite personality. F. D. Schleiermacher applies the phrase "the immortality of religion" to the religious emotion of oneness, amid finitude, with the infinite and, amid time, with the eternal. He denies any necessary connection between the belief in the continuance of personal existence and the consciousness of God, and bases his faith in immortality on Christ's promise of living fellowship with His followers, as presupposing their as well as His personal immortality. A. Schopenhauer assigns immortality to the universal will to live; and Feuerbach declares spirit or consciousness, eternal, but not any individual subject. R. H. Lotze lays down the broad principle, "All that has once come to be will eternally continue if it has an unchangeable value for the organic unity of the world, but it will obviously again cease to be, when that is not the case." (*Gr. der Psych.*, p. 74.)

Objections to the belief in immortality have been advanced from the standpoints of materialism, naturalism, pessimism and pantheism. Materialism argues that, as life depends on a material organism, thought is a function of the brain, and the soul is but the sum of mental processes dependent upon physical changes; therefore, the dissolution of the body carries with it necessarily the cessation of consciousness. That mind is correlated with brain and life with body must be conceded, but that they cease to be when their organs are destroyed has not been scientifically demonstrated. Indeed the following considerations may be advanced: (1) Man does distinguish himself from his body (in the primitive philosophy of animism the soul is already distinguished from the body); (2) he is conscious of his personal identity throughout all the changes of his body, and the fuller his personal development the more independent is his inner life of the outer; (3) in the exercise of his will he thinks himself as not controlled by but controlling his body, and the testimony of man's conscience to his liberty and responsibility is an ultimate datum of his consciousness. The theory of psychophysical parallelism has been subjected to a rigorous examination in James Ward's *Naturalism and Agnosticism*, part iii., and the argument that mind cannot be derived from matter convincingly presented. Sir Oliver Lodge in reply to E. Haeckel's *Riddle of the Universe* maintains that "life may be something not only ultra-terrestrial, but even immaterial, something outside our present categories of matter and energy; as real as they are, but different, and utilizing them for its own purpose" (*Life and Matter*, 1906, p. 198). He rejects the attempt to explain human personality as "generated by the material molecular aggregate of its own unaided latent power," and affirms that the "universe where the human spirit is more at home than it is among these temporary collocations of matter" is "a universe capable of infinite development, of noble contemplation, and of lofty joy, long after this planet—nay the whole solar system—shall have fulfilled its present spire of destiny, and retired cold and lifeless upon its endless way" (pp. 199-200).

In his lecture on *Human Immortality* (3rd ed., 1906), William James deals with "two supposed objections to the doctrine." The first is "the law that thought is a function of the brain." Accepting the law he distinguishes productive from permissive

or transmissive function (p. 32); and, rejecting the view that brain produces thought, he recognizes that in our present condition brain transmits thought, thought needs brain for its organ of expression; but this does not exclude the possibility of a condition in which thought will be no longer so dependent on brain. Against materialism three general objections can be offered: (1) the categories and the methods of physiology cannot solve the problems of psychology; (2) if physical energy is being transmuted into mental without any recovery, then the principle of the transmutation of energy is not universally applicable; (3) mind as the subject of knowledge cannot be derived from one of its objects, the very conception of which is a mental construction to account for some of the content of consciousness. Further arguments in the same direction are derived from the modern school of psychical research (see especially F. W. H. Myers' *Human Personality*, 1903).

Another objection is advanced from the standpoint of naturalism, which, whether it issues in materialism or not, seeks to explain man as but a product of the process of nature. The universe is so immeasurably vast in extension and duration, and man is so small, his home but a speck in space, and his history a span in time, that it seems an arrogant assumption for him to claim exemption from the universal law of evolution and dissolution. This view overlooks the facts that man has ideals of absolute value, truth, beauty and goodness, that he consciously communes with the God who is in all, and through all, and over all, that his mind recognizes the vastness of the universe and its universal law, and that such a mind, which perceives and conceives, must be greater than the object of its thought.

Pessimism suggests a third objection. The present life is so little worth living that its continuance is not to be desired. We cannot, however, admit that the history of mankind justifies this conclusion; for the great majority of men life is a good, and its continuance an object of hope. This philosophy when sincere, is often due to natural disposition, or to unfortunate circumstances, and in some cases is even a mental pose, a disguise of personal failure or disappointment.

For pantheism personal immortality appears a lesser good than reabsorption into the universal life. But against this objection we may confidently maintain that worthier of God and more blessed for man is the hope of a conscious communion in an eternal life of the Father of all with His whole family. Why should the infinite reality differentiate itself in finite personality if there is no permanent result; and why should finite personality be subjected to the often painful discipline of "self-knowledge, self-reverence and self-control," if no self-will be allowed to survive?

Lastly positivism teaches a corporate instead of an individual immortality; man should desire to live on as a beneficent influence in the race. But these possibilities are not mutually exclusive. A man may live on in the world by his teaching and example as a power for good, and he may also be continuing and completing his course under conditions still more favourable to all most worthy in him. Consciously to participate as a person in the progress of the race is surely a worthier hope than unconsciously to contribute to it as an influence; ultimately to share the triumph as well as the struggle is a more inspiring anticipation.

In stating constructively the doctrine of immortality we must assign secondary importance to the metaphysical arguments from the nature of the soul. It is sufficient to show, as has already been done, that the soul is not so absolutely dependent on the body that the dissolution of the one necessarily involves the cessation of the other. Such arguments as the indivisibility of the soul and its persistence can at most indicate the possibility of immortality. The argument for personal immortality must be based on some rational, moral, social or spiritual value which would be discredited if death ended all.

The juridical argument has some force; the present life does not show the harmony of condition and character which our sense of justice leads us to expect; the wicked prosper and the righteous suffer; there is ground for the expectation that in the future life the anomalies of this life will be corrected. Although this argu-

ment has the support of such great names as Butler and Kant, yet it will repel many minds as an appeal to the motive of self-interest.

The ethical argument has greater value. The more lofty man's aims, the more worthy his labours, the more incomplete his life appears to be. The man who lives for fame, wealth, power, may be satisfied now; but he who lives for the ideals of truth, beauty and goodness, lives not for time but for eternity, and his life cannot be fulfilled on this side of the grave. Unless these ideals are mocking visions, man has a right to expect the continuance of his life for its completion. This is the line of argument developed by Hugo Münsterberg in his lecture on *The Eternal Life* (1905).

More general in its appeal is the argument from the affections, which has been beautifully developed in Tennyson's *In Memoriam*. The heart protests against the severance of death, and claims the continuance of love's communion after death; and as man feels that love is what is most godlike in his nature, love's claim has supreme authority.

There is a religious argument for immortality. A difference of opinion exists among scholars regarding the indications of a hope of immortality based on the consciousness of fellowship with God in the Old Testament (see article on ESCHATOLOGY). The proof offered by Jesus Himself when He declares God to be the God of the living and not of the dead (Matt. xxii. 32) is this: God has entered into personal relations with man, and as He is the Eternal, He will preserve in life with Himself those who are thus in communion with Him. The infinite value of every individual soul (Luke, xv.) to God as Father is an assurance that He will not suffer the loss in death of any of His children. Josiah Royce in his lecture on *The Conception of Immortality*, 1900, (pp. 145-146), combines this argument of the soul's union with God with the argument of the incompleteness of man's life. It must be pointed out, however, that these arguments, based on personal values, do not afford a proof of natural immortality, but of what has been called conditional. Those will survive who deserve to survive. As adaptation to environment is the condition of the survival of any organism, so human personality can attain immortality only as it adapts itself to God, the eternal environment. This is the argument developed by J. G. Simpson in his two books, *Man and the Attainment of Immortality* (1922) and *The Spiritual Interpretation of Nature* (1912).

R. W. Emerson declares that "the impulse to seek proof of immortality is itself the strongest proof of all." We expect immortality not merely because we desire it; but because the desire itself arises from all that is best and truest and worthiest in ourselves. The desire is reasonable, moral, social, religious; it has the same worth as the loftiest ideals, and worthiest aspirations of the soul of man. The loss of the belief casts a dark shadow over the present life, a potent moral influence is gone. "The day," says Ernest Renan, "in which the belief in an after-life shall vanish from the earth will witness a terrific moral and spiritual decadence. Some of us perhaps might do without it, provided only that others held fast. But there is no lever capable of raising an entire people if once they have lost their faith in the immortality of the soul" (quoted by A. W. Momerie, *Immortality*, p. 9). To this belief, many and good as are the arguments which can be advanced for it, a confident assurance is given by Christian faith in the Risen Lord, and the life and immortality which He has brought to light in His Gospel.

IMMUNITY (see also BACTERIA AND DISEASE). The term "immunity" is used in science in the technical sense. An animal is described as *naturally immune* against the microbe of a disease if the microbe in question cannot establish itself in the organism

and as *artificially immune* if it was naturally susceptible and has been rendered insusceptible. Similarly, an animal is described as *naturally immune* against a poison if its organism is naturally proof, and as *artificially immune* if its organism has been rendered proof against the poison.

Natural Immunity.—A few words may be said first with respect to natural immunity against infection. We may attribute the fact that the body normally remains free from microbic infection to a conjunction of causes:—(i.) to the fact that its external and internal coatings furnish mechanical protections against infection (this point need not be further considered here); (ii.) to the fact that the body is equipped with special machinery for the destruction of microbes (the nature of this machinery will be discussed below in connection with acquired immunity); (iii.) to the fact that certain of the conditions which normally prevail in the animal organism are inimical to the growth of microbes as a whole or at any rate to the growth of certain classes of microbes. Of the conditions here in question two which are of quite dominant importance were discovered in the course of researches on wounds carried out in the World War.

Antitrypsin.—The first and more generally important is the antitryptic power of the blood fluids. Such antitryptic power will in every case hamper, and in the ordinary case completely inhibit, bacterial growth. It will achieve this by neutralizing, in part or completely, the digestive ferments of the microbes which would otherwise convert the unassimilable native albumens of the blood-fluids and serous discharges into assimilable nutrient materials. Antitrypsin in the blood fluids will therefore mean for the microbes therein implanted, either a restriction of their food supply, or complete starvation. The facts, as far as known, all comport with this inference.

Only a few species of microbes (the staphylococcus, streptococcus, pneumococcus and perhaps the microbes of all genuinely septicæmic diseases) can proliferate in antitryptic blood fluids. Further, these microbes (*serophytic* microbes) produce when grown in plasma (generalizing from observations made with staphylococcus and streptococcus) trypsin which quenches the antitryptic power of the surrounding blood fluids and then digests vacuoles in the surrounding clot. Again, all serophytic microbes grow very much more vigorously (the streptococcus for example very many thousand times more vigorously) in the blood fluids when these microbes have, by an artificial addition of trypsin, been relieved from the task of themselves producing enough trypsin to quench the antitryptic power of the surrounding medium. And finally, all those kinds of microbes which are unable to grow in antitryptic blood fluids begin to pullulate there the moment trypsin is added—and let it be noted here that a spontaneous addition of trypsin occurs regularly in wounds as soon as the emigrated leucocytes are broken down under the influence of bacterial growth and unfavourable external influences.

Effect of Alkaline Reaction.—Again—and here the second of the restraints on microbic growth spoken of above comes into question—in the course of research work on wound infections conducted in the course of the war, it was established, in connection with the microbe of gas gangrene, that the proliferation of this bacillus in the blood fluids and serous effusions is inhibited not only by the antitryptic power but also by the normal alkaline reaction of these media. Proof of this is furnished by the fact that as soon as the alkaline reaction in question is blunted off by the ante- or post-mortem formation of lactic acid in muscles deprived of their blood supply, or more directly by an infusion of any acid into the blood, the bacillus of gangrene multiplies without restraint.

Natural Susceptibility.—The problem as to why a particular animal is naturally susceptible to particular poisons is likewise a chemical problem, but a chemical problem of a different order. Formulated in the technical terms which were introduced by Ehrlich the problem is that as to why the tissues of the insusceptible animal contain no *receptors* for the poison, that is to say, no organic substratum upon which that poison can anchor itself. This is a question of the aboriginal chemical constitution of the body—a question as to why a particular species of animal was constructed

of one kind of elements rather than of another.

Acquired Immunity.—The problem presented by acquired immunity to infections or poisons differs in important respects from that presented by natural immunity. With respect to such reinforcement of the natural resistance it will be well to note at the outset (a) that it can be achieved apart from any violent physiological commotion; (b) that acquired immunity does not betray itself in any altered habit of body; and (c) that the condition may in many cases be presented to-day and gone to-morrow. All these facts indicate that the acquired immunity cannot involve anything in the nature of a revolutionary physiological upheaval such, for example, as a fundamental alteration in the blood elements, or a cutting out of receptor elements from cells.

Anticipating, we may say that later it will be shown with regard to acquired immunity to infections that this depends upon the development of (a) increased antibacterial substances in the blood fluid, (b) increased efficiency in the leucocytes and (c) increased capacity for producing antibacterial substances in response to infection. Similarly it will be shown with regard to acquired immunity to poisons that this depends upon the appearance of neutralizing elements (so-called antitoxins) in the blood coupled with the acquirement of increased capacity for elaborating these elements in response to an incorporation of the corresponding poisons.

Confining ourselves to the problem as to how the bacterial infections are combated in the organism, we may begin by considering the two chief opposing doctrines which were promulgated, when, under the prompting of Pasteur's practical achievements in the field of prophylaxis, problems of immunity began to be first seriously considered. These theories included natural as well as acquired immunity.

Humoral Theory.—In the theory which goes by the name of the humoral theory, natural immunity is attributed to the bactericidal substances contained in the normal blood fluids, and acquired resistance to the acquisition or increase of such bactericidal power. The general thesis, at any rate, of this theory stands secure. Where microbes are killed otherwise than by physical agencies or by inanition, their destruction must inevitably result from some form of chemical action. So, too, the acquisition of greater power of destruction must of necessity be imputed to the achievement of more potent chemical powers. On the other hand, it cannot of course be certain *a priori* that the antibacterial elements concerned in the destruction of microbes will be found in the blood fluids and only in these. That the blood fluids do, in point of fact, possess bactericidal power was demonstrated by Fodor and Nuttall, and it was at first thought, though a careful study of Nuttall's results should have prevented this, that such bactericidal action was exercised upon microbes without distinction of kind. Later research has, however, shown that the blood fluids are directly poisonous only for certain species of microbes such, for example, as the typhoid bacillus and the cholera vibrio. Certain other species of microbes, and in particular the microbes of specifically septicæmic diseases are, as we have seen, serophytic—the number that grow out in serum being as great as the number which grow out in the best artificial nutrient medium. Thus, the so-called humoral theory, though it would account for the organism possessing considerable resistance to typhoid and cholera, leaves unexplained the fact of the normal organism offering very considerable resistance to serophytic microbes.

What applies to natural, applies also to acquired immunity. There is nothing to show that increased resistance to serophytic microbes and septic infections generally is accompanied by the development of any bactericidal power in the blood fluids.

Phagocytic Theory.—An entirely different conception of immunity is that familiarly known as Mechnikov's *theory of phagocytosis*. In the humoral theory the problem of immunity is envisaged from the point of view of the bacteriological specialist and to some extent also from the standpoint of the chemist. Mechnikov for his part approached the problem from that of the morphologist who takes the whole field of animal life as his province. His theory of immunity therefore starts with the generalization that the Protozoa feed upon the lower forms of life such as

microbes. It further regards the fact that the higher animals have been evolved out of colonial aggregations of Protozoa. In every such colonial aggregation certain of the associated cells instead of becoming specialized persist in the condition of wandering cells.

With regard to these free-living members of the protozoal colony Mechnikov divined that they function as defensive cells. And he showed in connection with sponges and other invertebrates that these wandering cells collect round invading microbes and other foreign intrusions and that they thereafter proceed to ingest and digest them or to aid otherwise in their elimination. Lastly Mechnikov pointed out that the leucocytes of the vertebrate were homologous to those wandering cells and performed exactly the same defensive offices. In particular when leucocytes emigrate from the capillaries into a focus of bacterial infection, in the normal case, they follow this up by ingesting the intruding micro-organisms, and killing them intracellularly. *Natural* or *native immunity* was thus, in the conception of Mechnikov, due to efficient leucocytic functioning; and *acquired immunity* to the leucocytes having by a *process of training* (as he called it) acquired a power of more effectively confronting, ingesting and destroying microbes.

Eclectic Theory.—The central tenet of the Mechnikov theory—the tenet that the leucocytes play a very important rôle in the defence of the body against infection—has now found universal acceptance, but at the same time the doctrine that resistance to infection depends in every case on the action of the leucocytes has proved untenable. In connection with the defence of the organism we must distinguish between (1) defence against infection by serophytic microbes, that is against microbes which like the streptococcus and staphylococcus proliferate in the normal serum; (2) defence against infection by microbes incapable of multiplying in the antitryptic normal serum but not directly killed by it, and (3) defence against microbes directly killed by the serum.

In connection with the first kind of microbe the fact that although they grow freely in the serum and plasma, these are killed in large numbers in the blood and in the serum, when living leucocytes are added, shows that the cellular elements of the blood here do the work of destruction.

In connection with the successful killing of these microbes, the leucocytes must, however, in all cases have free mechanical access to the microbes. There would for example be default in this respect if, as would happen in dealing with infected defibrinated or infected centrifuged blood *in vitro*, the leucocytes settled to the bottom and the microbes were buoyed up out of their reach in the serum. The same would of course happen *in vivo* in all serous effusions.

In connection with those microbes which are not directly poisoned but fail to proliferate in the serum, the most important restraining influence is the native antitryptic power of the blood, but once the antitryptic inhibitory action of the blood fluids and serous effusions has been neutralized the leucocytes, even when everything else favours them, will be impotent to inhibit microbic growth. On the contrary as soon as the leucocytes degenerate they will furnish a further quantum of trypsin and in this way directly conduce to the pullulation of all manner of microbes.

Lastly, the leucocytes do not seem to contribute to the defence of the organism against those microbes which, like the typhoid bacillus and the cholera vibrio, are directly poisoned by the serum. When we implant such microbes into defibrinated blood and then incubate and make microscopic preparations those microbes which are quickly ingested are found intact within the phagocytes while those which are left exposed to the action of the serum are distorted and dissolved. And again, when living emigrated leucocytes are brought to bear upon typhoid bacilli it would seem that few of the microbes are killed. Precisely similar results are obtained with extracts made from leucocytes. It was shown by Schattentfroth that such extracts exert bactericidal action upon the staphylococcus and streptococcus while they exert no such action upon the typhoid bacillus and the cholera vibrio. And again it was shown by Colebrook that the products of inflammation derived from foci of inflammation set up by incorporating into rabbits

lint soaked in typhoid vaccine are powerfully bactericidal for the staphylococcus and streptococcus while for the microbes of typhoid and cholera they are not more bactericidal than ordinary serum.

This review of the facts shows that only in the case of serophytic microbes does the defence of the body depend upon the leucocytes and that when it is a question of defence against the other two classes of microbes (those whose growth is entirely inhibited and those which are directly poisoned by the serum) the leucocytes are either impotent or directly harmful.

Leucocytes Concerned in Immunization.—Mechnikov originally taught that the leucocytes were attracted to microbes and induced to phagocytose them by the toxin secreted by the microbes; and that there was here only an interaction between leucocytes and microbes and that the blood fluids could be left entirely out of the story. That that doctrine cannot be sustained can be demonstrated by a simple experiment.

We begin by receiving a sample of blood taken direct from the vessels into normal salt solution. We then centrifuge and recentrifuge in further volumes of this normal salt solution so as to wash the cellular elements free from all traces of the blood fluids. We then make two so-called *phagocytic mixtures* combining in the one case (a) one volume of a bacterial suspension with (b) one volume of washed leucocytes and (c) one volume of 0.85% salt solution; and in the other case (a) one volume of washed leucocytes, (b) one volume of the same bacterial suspension and (c) one volume of *normal serum*. These mixtures are then placed in the incubator and after a suitable lapse of time a sample of each is examined under the microscope. In the first phagocytic mixture—that in which no serum was employed—the leucocytes have failed to ingest any microbes. In the specimen in which serum has been employed, the microbes have been plentifully ingested. This result depends not upon any stimulating effect exerted upon the leucocytes, but upon the fact that the serum has effected a chemical change—a so-called *opsonic change*—in the microbes. That this opsonic change does not in any sense affect the vitality of the microbe is shown in the case of serophytic microbes by the fact that the serum that exerts an opsonic effect furnished culture medium in which the affected microbes will all grow out into colonies. The blood fluids intervene further in the destruction of microbes in the interior of the phagocyte by combining with them in such a way as to favour their intracellular digestion. This action, which was first described by Douglas, is known as the protryptic action of the blood fluids.

The living leucocyte can also kill microbes apart from phagocytosis. The following experiment is instructive. A shallow receptacle is filled with a solid nutrient medium whose surface has been uniformly implanted with staphylococcus or streptococcus. The centre portions of the three cover glasses are thickly carpeted with living leucocytes obtained direct from the blood. We now, after different treatment, impose these cover glasses side by side upon the implanted nutrient surface. In the case of the first cover glass the adhering leucocytes are brought into application in conjunction with the adhering serum; in the case of the second they have been washed free from every trace of serum; and in the case of the third cover glass the adhering leucocytes, instead of being employed living, have been killed by drying.

The whole preparation is now incubated at blood heat for 12 hours or more. The microbes will then be found to have grown out forming an uninterrupted sheet of colonies over the whole surface of the nutrient medium except under those areas of cover glasses 1 and 2 which are carpeted with living leucocytes. Here the implanted microbes have not proliferated, and microscopic examination of the cover glasses shows that where the leucocytes came into action in conjunction with serum the microbes are all lying intracellularly; while where the leucocytes were washed free from serum, the microbes are all lying extracellularly. The experiment thus shows that microbes can be killed by leucocytes both intra- and extra-cellularly, *i.e.*, both by phagocytosis and also apart from phagocytosis. This holds true both under the conditions obtaining in this particular experiment, and also in numerous other conditions. That destruction of microbes by leucocytes without the

intervention of phagocytosis occurs also very frequently *in vivo* is practically certain.

Results of Experiments.—Research has thus shown that the destruction of microbes in the body does not proceed only along the lines laid down in the humoral and phagocytic theories. Instead of there being, as was assumed in those theories, only one physiological device by which microbes without distinction are killed in the organism, nature would appear to provide different distinctive devices for different microbes. Some pathogenetic microbes are combated by the bactericidal action of the serum unassisted by the leucocytes, others again are prevented from proliferating by special agencies, such for example as the antitryptic power of the blood; and again a third description of microbe, the serophytic microbes, are destroyed intracellularly and extracellularly by the leucocytes aided, or unaided, by the blood fluids.

The above deals only with the normal protective machinery of the body as distinguished from that which comes into play in artificial immunity. In connection with the latter Metchnikov, as will be remembered, taught that acquired resistance was due not to any changes in the blood fluids, but to the leucocytes having been subjected to a process of training which gave to them a greater capacity for confronting and ingesting microbes. This doctrine had to go by the board when it was shown in numberless cases that increased phagocytosis goes hand in hand with increasing opsonic power in the blood fluids.

From this it was incautiously assumed—though this tenet was never definitely formulated—that the leucocytes constitute in artificial immunity an invariable, and the blood fluids the only variable, factor. That the phagocytic efficiency of the leucocytes was also a variable factor was first shown by Shattock and Dudgeon, who observed that the phagocytic efficiency of the patient's leucocytes is in many cases of pyrexial infection greater than that of the normal man. The phagocytic efficiency of a patient's leucocytes may also, as was further shown by Shattock and Dudgeon, be less than normal.

These observations have a direct bearing upon Metchnikov's doctrine with respect to acquired immunity, since, in all infections associated with constitutional disturbances, antigens from the foci of infection are being brought into operation—in other words the organism is experiencing and is reacting to *auto-inoculations*. It follows that, conformably with the doctrine of Metchnikov, the leucocytes should in every case of pyrexial infection be conducted by successive degrees to a condition of continually increased phagocytic efficiency. Instead of that these cellular elements are, sometimes in localised infections, and practically always in streptococcus septicaemia, reduced to a condition of diminished efficiency.

Artificial Immunization.—We have to consider next how to increase the effectiveness of the antibacterial machinery, *i.e.*, how to produce artificial immunization against infection. The original point of departure was the observation that those patients who had contracted and recovered from an infectious disease were thereby rendered proof against reinfection. That observation led, in connection with smallpox, to the adoption of a procedure for the warding off of the disease. The procedure adopted in various parts of the world and introduced to Europe from Turkey, consisted in the implantation into the susceptible individual of material obtained from a patient suffering from smallpox. This procedure, which was denoted inoculation because it resembled the grafting of an *eye* or *bud* into a new stock, is in reality the parent from which all other procedures of artificial immunization are derived. What required still to be done was to purge inoculation of its dangers and to regulate the immunizing stimulus. This was successfully done in Jennerian vaccination. But the achievement of Jenner was in point of fact purely empirical.

Pasteur's Work.—After Jenner came Pasteur and with Pasteur scientific methods are for the first time brought into application in connection with prophylactic inoculation. His initial achievement was to recognise that the essential in Jennerian vaccination was that for a virulent infective organism obtained from actual cases of smallpox there has been substituted an infective

organism which by the operations of nature—to wit by transfer to the cow—had been attenuated in such a manner as to render it non-lethal for man. By the exploitation of that general principle, by the employment of pure culture and by a technique of artificial attenuation adapted with infinite resource to each separate case, the whole series of Pasteurian successes in the field of artificial immunization were one after another achieved. Artificial immunization was not, however, purged from all its risks by the procedures of Pasteur.

It had not yet been transformed into a scientifically regulated procedure. The Pasteurian vaccines were in point of fact standardized only thus far that recourse to attenuation placed in each case a certain limit upon the proliferation of the vaccinating material in the organism of a normally resistant man or animal.

Standardization.—A great step in advance was taken when it was established in connection with anti-typhoid inoculation that the antigen required for the setting in motion of the machinery of immunization can be furnished by the incorporation of sterilized microbic cultures. And further, important steps to the achievement of a standardization of bacterial vaccines were made when a technique for the enumeration of the microbes in bacterial suspensions was devised, and when it was recognized that weighed quanta of desiccated and powdered bacterial substance could be employed in cases where, owing to the felting together of the microbes, enumeration of the microbial suspension was impracticable. The counting of the microbes or the weighing of the bacterial substance is, however, only a means to an end—the standardization of a vaccine, *i.e.*, the determination of the doses which will give the best “curve of immunization.”

The Curve of Immunization.—The expression *curve of immunization* calls attention to certain fundamentally important points in connection with the reaction of the body to the incorporation of vaccines. In the pre-Pasteurian and Pasteurian periods, when ideas about the nature of immunizing response were still vague, it was assumed with regard to vaccines that they produced their effects only after a certain incubation period (ordinarily only after ten days). And it was further taken for granted that the curve of immunization would from the beginning move always in the upward direction. When, however, immunization curves came to be constructed (and this was done first in connection with anti-typhoid inoculation) unanticipated features revealed themselves and in connection with these also time-relations which did not conform with expectation.

Negative and Positive Phases.—In what may be called the normal case—*i.e.*, in the case where the dose of vaccine inoculated is sufficient to produce an appreciable constitutional disturbance, a bi-phasic curve of immunization is obtained. For 24 or more hours after the inoculation the antibacterial power of the blood is reduced. This—the so-called negative phase—is followed by a phase of increased antibacterial power—the so-called positive phase—which may last for one or two or a number of days as the case may be. After this the antibacterial power falls away gradually to a level only slightly higher than the original normal. But despite this there would seem to persist in the organism (and this would seem to be the chief profit from inoculation) a power of making more rapid and more ample immunizing response to any subsequent incorporation of antigen whether in the form of a subsequent inoculation of a similar vaccine, or actual infection.

When, instead of a quantum of vaccine which produces a constitutional disturbance, a smaller dose is inoculated, the negative phase is elided and a positive phase is well developed already 24 hours after the incorporation of the vaccine. And, finally, when excessive doses of vaccine, such as produce very severe constitutional disturbances, are incorporated, the negative phase may be correspondingly intense and may persist for many weeks. These facts have an important bearing upon prophylactic operations; they must also, as reflection will show, have an importance in connection with the immunization procedure to which horses are subjected with a view to their producing antibacterial and antitoxic sera. Again substantially the same relations as between the quantum of vaccine inoculated and the type of response elicited, obtain in the case where vaccines are inoculated into patients who

are the subjects of infection. But in that case the conditions are so far different that we have to consider in each case two quanta of antigen: that administered in the vaccine, and that already contained in the patient's organism. Where a patient is the subject of only a minimal infection, we may employ doses of vaccine nearly as great as those employed for the prophylaxis of healthy men. Where a patient is heavily infected, we are restricted to the employment of minimal doses, and finally, when the patient is already labouring under an excessive infection, the injection of vaccines can only do harm.

The principle that the kind of response, and the amplitude of the reaction, and the time-relations of the phases are in each case a function of the quantum of antigen brought into application is found to apply also to the case where the vaccine is added to the extravascular blood. We obtain *in vitro* every variety of effect according to the dose of vaccine brought into application and the time for which it operates upon the blood—the effects varying from an instantaneous increase of bactericidal power to a loss of most of that destructive power. And further different effects are obtained according as we select now one and now another method of testing. We obtain for example one result when we measure the bactericidal power of the whole blood; another when we measure the opsonic power of the serum; a third when we measure the phagocytic efficiency of the leucocytes.

The lessons which can be drawn from immunization curves may now be summarised. The first of these is that excessive doses of vaccine may delay and possibly interfere with the prophylactic response, and further that such excessive doses of vaccine administered to patients suffering from an infection may definitely aggravate their condition. Other important lessons are that when appropriate doses of vaccine (*i.e.*, doses which are not followed by a negative phase) are administered, prophylactic effects may be obtained almost immediately after inoculation. And further it should be possible to arrest a general infection by inoculating in the incubation period and then employing a reduced dose of vaccine.

Considerable evidence showing that immunization develops very rapidly after the inoculation of an antigen is furnished in the work of Pirquet. If a first implantation of vaccinia is followed by similar implantations on successive days, the response to these latter differs from the response made to the first. This altered clinical response—which would appear to indicate a more rapid destruction of the later implanted infective material—was described under the name of *allergy*. It was further shown by Pirquet in connection with the inoculation of foreign serum that the supervening clinical reaction—which appears to indicate the throwing out of that foreign serum from the blood—is accelerated when the injection of serum is made into an organism which has been before subjected to that procedure. The interval between the injection of the foreign serum and the clinical manifestations associated with its elimination from the blood (normally 10–14 days) may be reduced to a very few minutes.

A series of further questions in relation to artificial immunity have to be considered (1) Are there agencies other than vaccines proper—in other words, other than living or dead microbes or substances derived from the bodies of microbes—which will affect the bactericidal power of the blood and leucocytes? (2) Again, are the antibacterial substances in the serum specific in the sense of operating only upon one particular variety of microbe or are they non-specific? (3) Further, will leucocytes which have acquired increased phagocytic efficiency, ingest more actively only one particular species of microbe, or all microbes without distinction? (4) Finally, what are the cells in the body which elaborate the anti-bacterial substances? All these questions are intimately linked up.

Non-bacterial Vaccine.—In connection with the question as to whether there are agencies other than vaccines proper which can increase or, as the case may be, diminish the bactericidal power of the blood, it has been shown that the infliction of burns increases the bactericidal power of the serum for the anthrax bacillus. This increased bactericidal power is no doubt referable to an absorption into the blood of disintegration products derived

from the burnt tissues. Again, it has recently been ascertained that increased bactericidal power can be developed in the blood *in vitro* by adding to it foreign sera and also non-foreign sera artificially altered by heating to 60° C. Lastly, it has been shown in connection with the irradiation of the skin with ultra-violet light, the light of the electric arc and sunlight, that by these agencies also the bactericidal power of the blood is increased, such increased bactericidal power depending upon an increased phagocytic power of the leucocytes and also an increased antibacterial power in the serum (*see* HELIOTHERAPY and PUBLIC HEALTH). It is not yet known how irradiation produces these results, but the consideration that radiations such as are here in question are much more likely to act by breaking down than by building up albuminous substances, taken together with the fact that increased bactericidal power is achieved only with a certain quantum of irradiation and that the blood suffers deterioration when larger doses are employed, would seem to point to the conclusion that we are here, in each case, dealing with effects produced by the absorption into the blood of an antigen in the form of disintegration products generated by the irradiation.

Specificity.—The non-bacterial antigens which have been under discussion above occupy at present a position apart in the respect that it would generally be held with regard to these that they might quite likely evoke a non-specific immunizing response; whereas it would be generally held that bacterial vaccines would produce only specific immunizing response. But against this there is conclusive evidence to show that bacterial vaccines also evoke non-specific immunizing response in the form of increased bactericidal power in the blood, increased phagocytic efficiency in the leucocytes and sometimes also increased antibacterial power in the serum. Thus, for example, by the incorporation of staphylococcus the blood can be rendered more bactericidal for streptococcus. This can be achieved also by the addition of staphylococcus vaccine to the blood *in vitro*. Similarly an addition of tuberculin to the extravascular blood will increase the bactericidal power of the blood to staphylococcus, increasing at the same time the phagocytic efficiency of the leucocytes.

These laboratory experiments are in consonance with the statistical results obtained in connection with anti-pneumococcus inoculations at the Premier Mine in the Transvaal. Here in 1912, in addition to a striking reduction in the incidence and death-rate of pneumonia, there was achieved a striking reduction in the incidence and death-rate from "other diseases."

Derivation of Immunization Product.—The discussion of the deeper problems as to where antibacterial substances are elaborated in the body, and as to how their production is to be explained, may be deferred for a moment. For the facts relating to immunization against bacterial toxins must first be taken into consideration by bringing out the following points: (1) The machinery of immunization is in reality a machinery for neutralizing or otherwise disposing of poisonous substances—poisonous substances being by definition those which enter into crippling or lethal chemical combination with the blood fluids and tissues. (2) The machinery of immunization achieves its ends by furnishing substances which enter into neutralizing or precipitating or destructive union with the poisonous substances above spoken of. (3) The machinery of immunization is brought into operation only by a particular class of poisons—to wit, by those which enter into crippling but not immediately lethal chemical combination with the cellular protoplasm—those which, to use the expressions of Ehrlich, intrude themselves into the "side-chains" and not into the "vital ring" of that protoplasm. Of such poisons four kinds specially invite attention. These are: (a) the poisonous constituents of the bacterial protoplasm, (b) the albuminous substances contained in foreign sera and certain other foreign albuminous substances, (c) bacterial toxins such as those which can be filtered off from cultures of diphtheria and tetanus and (d) vegetable and animal toxalbumens such as abrin, ricin and the various snake venoms. With respect to the first the body responds to their inoculation by a production of *bacterio-tropic substances*, *i.e.*, substances which enter into detrimental or lethal chemical combination with bacteria. The inoculation of sera is followed

by the elaboration and delivery into the blood of *sero-tropic substances* which neutralize and precipitate these sera. The inoculation of bacterial toxins in like manner—this discovery was made by Behring—leads to the production and delivery into the blood of toxitropic substances. These, known as bacterial *antitoxins*, neutralize and precipitate the corresponding toxins. And, finally, the inoculation of toxalbumens is followed by an elaboration and delivery into the blood of the appropriate neutralizing substances.

Practical Results.—The discovery of bacterial antitoxins had led to important practical applications in connection with the treatment and prophylaxis of, in particular, diphtheria (*see INFECTIOUS FEVERS*) and tetanus (*q.v.*). By virtue of the fact that toxins and antitoxins lend themselves to accurate quantitative study, it has contributed much to our knowledge of the machinery of immunization. It was through the study of the curves of immunizing response made to the inoculation of tetanus toxin that the negative phase first became known. Again, it was by the study of antitoxin production that it was for the first time unequivocally established that the organism which has made previous response to even a minimal quantum of a toxin is thereafter capable of responding to any further quantum of that poison with a prompter and ampler elaboration of antitoxins.

Further, by the study of the antitoxin content of the blood in its relation to diphtheria toxin, it has been shown that the presence of even a small quantum of antitoxin in the blood protects against infection, and that the insusceptibility of the majority of adults to diphtheritic infection is correlated with the possession of a minute quantum of antitoxin derived, as it would seem, from repeated minimal diphtheritic infections contracted in their earlier life. The same would appear to hold also of the scarlet fever streptococcus. We have here, as reflection will show, facts which illuminate the epidemiology of diphtheria and scarlatina and show that it is possible and may under circumstances be advisable to substitute for a prophylactic inoculation of a bacterial vaccine, an injection of antitoxin, or alternatively an injection of such quantum of toxin as will evoke an antitoxic response.

Two further points about antitoxins have important bearings upon the problem as to where and how products of immunization are produced in the organism. (1) Antitoxins are quite rigidly specific—each antitoxin neutralizing only the particular kind of toxin in response to which it was engendered. (2) After a first inoculation of toxins antitoxins are only very slowly produced. Ordinarily an interval of ten to 20 days elapses before they make their appearance in the blood.

These properties are not, let it be noted, differential properties of antitoxins; they characterize also certain kinds of bacteriotropic substances. Specificity and comparatively tardy appearance in the blood characterize for example agglutinins, and the so-called "thermostable immune bodies."

Since there are two kinds of products of immunization: one kind that are eminently non-specific and are produced immediately (and can, as we have seen, be produced in the blood *in vitro*); and another kind which are rigidly specific and are elaborated only after a considerable lapse of time and are so far as appears produced only *in vivo*; we may now seek for an answer to the problem as to how and where these various products of immunization are engendered. Since it may be taken as certain that these two kinds cannot well originate in the same cells and be engendered by the same kind of metabolic operation, we may divide up the problem and consider first by what cells and by what kind of metabolic operation the non-specific anti-bacterial substances are produced and then take up the question as to where and how antitoxins and such antibacterial substances as are specific are generated.

Non-specific Antibacterial Substances.—The former question presents no difficulty. The facts set forth above make it clear that non-specific antibacterial substances are elaborated by the leucocytes. And further the facts suggest that the leucocytes produce these substances as ordinary secretion incited by the chemical products derived from bacterial and cellular disintegration products applied in suitable concentration.

Further the facts comport with the idea that leucocytes which have elaborated antibacterial secretions but have not as yet excreted these into the environing blood fluids will, by virtue of their increased content in antibacterial substances, possess increased antibacterial efficiency, while the blood fluids will not have gained anything in antibacterial power.

Conversely leucocytes that have excreted their antibacterial substances will exhibit diminished antibacterial power and the blood fluids which have received these secretions will have received an accretion of antibacterial power.

Specific Products of Immunization.—The problem as to how these products of immunization which indure chemically with only one counterpart substance are engendered in the body, is of quite another order of difficulty, and it is one of the memorable achievements of Ehrlich to have conceived how the furnishing of such specific products of immunization could be accounted for. The problem presented itself to Ehrlich's mind in the following vivid manner: "If," it was thus that Ehrlich communed with himself, "If I take a guinea-pig—that is to say, a creature whose country of origin is Southern America—and administer to it abrin—a poison derived exclusively from Africa (and thus one which neither the tame guinea-pig nor its ancestry can ever have encountered) and if I now find that my guinea-pig furnishes me with an antidotal substance which indures with the abrin as does a key with the wards of the lock for which it is made, is there then for me any way of escape from the conclusion that the organism of my guinea-pig has specially constructed an antidotal substance to fit the particular kind of poison I have administered—performing in this a feat of chemical analysis and synthesis which would baffle the ablest chemist?" From the intellectual *impasse* into which this interrogatory seemed to lead there was, Ehrlich discerned, a possible way of escape. He reflected that there must of necessity exist in the organism of any animal which is affected by a given poison a counterpart substance (or to use his technical term) a *receptor* which enters into chemical combination with that poison. In other words, there must exist already preformed in the organism of susceptible animals, substances which have a chemical constitution such as would admit of their functioning as antitoxins.

At the same time these counterpart substances differ fundamentally from the non-specific antibacterial substances which were considered above. First of all they are not, as are the substances last mentioned, available in the form of secretory products produced only with a view to their being ejected from the cell. Instead of that, specific counterpart substances are integral elements of the cellular protoplasm, and elements of which it may be assumed with certainty that they subserve special functions in the internal economy of the cells of which they are constituents. Further the specific counterpart substances we are here considering differ from the non-specific antibacterial substances in the respect that while these latter are elaborated only in one particular variety of cell (to wit, in the leucocyte) the former are widely distributed in the organism, being located in each case in a different assortment of cells. Thus, for example, the counterpart substances to which the diphtheritic toxin would anchor itself would be located in a different assortment of cells than the counterpart substances with which the tetanus toxin would combine. And again the counterpart substances which would combine with abrin would be different. This would hold true also of the counterpart substances which would unite with the poisons derived from each particular variety of bacterial protoplasm.

So far it has been shown only that susceptible animals must by the very nature of things contain in their cell-protoplasm constituent elements which are the exact chemical counterparts of poisons. We are still very far from the solution of the mystery (a) of the organism furnishing antitoxins in the circulating blood; (b) of its furnishing antitoxins only to special classes of poisons; and (c) of its furnishing these in quantities far in excess of the quantum of counterpart substances originally contained in the organism. Ehrlich, in exploring for some way of exit from the labyrinth constituted by these questions oriented himself by the

aid of a ground-plan, in which there was set out his general conception of the stereo-chemistry of protoplasm. In the plan in question the protoplasm is a structure made up of side-chains assembled round a central ring—the continued life of the protoplasm depending upon the integrity of the central (or as we may call it *vital*) ring; while the side-chains consist of elements which are integrated into the protoplasm for its nourishing and vital functioning. To this original ground plan there was now added by Ehrlich a new feature. The conception which he now added was that the side-chains of the protoplasm would, as soon as they became redundant, be cast forth from the cell into the circulating blood, forming there what he called *free receptors*.

Interpreted in the light of this so-called *side-chain* theory, the incorporation of poisons which make a chemical attack upon the vital ring of the cell protoplasm would abrogate the life of the cell and would therefore be incompatible with an elaboration of antitoxins. The situation is entirely different when the poison, instead of directing its attack to the vital ring, anchors itself on to one of the side-chains. After a temporary putting out of action of those functions which are discharged by the particular side-chains in question, this would lead to the replacement of the crippled side-chains, and thereafter to a hyper-replacement and to such redundancy of these in the protoplasm as would involve casting forth these side-chain receptors into the circulating blood. This theory, which is quite as applicable to the production of specific antibacterial substances as to the production of antitoxins—would seem to lie open to critical assault in that the hyper-replacement of side-chains does not necessarily conduct to an excretion of these into the circulating blood. In point of fact in the case of muscle, on which Ehrlich here relies, it leads to something very different, to a hypertrophy of this tissue.

Finally, the side-chain theory has met with hostile criticism more especially on the ground that it would compel us to believe that the noble tissues, such as those of the central nervous tissue which are poisoned by the toxins of diphtheria and tetanus, can be converted into secretory organs so prolific as to furnish in the blood tens and hundreds of thousands of units of the corresponding antitoxins. The side-chain theory does not in any way require us to believe this. It would do so only if it had been established that poisons such as diphtheria and tetanus toxins attack only the central nervous system. But in point of fact Ehrlich assumed that the poisons which are responded to by a production of antitoxins are all *polytropic*—in other words they turn towards and combine chemically with a number of different tissues. So far therefore as the side-chain theory is concerned, we are thus authorised to assume that, not the cells of the central nervous system, but all or any of the other and less noble tissues which are affected by the toxins, are those which produce the harvest of antitoxins.

IMMUNITY, in law, a term for exemption from liability, principally used in the legal sense in connection with extritoriality (*q.v.*).

IMOLA, a town and episcopal see of Emilia, Italy (anc. *Forum Corneliū*), province of Bologna, 21 m. southeast of that town by rail, 140 ft. above sea-level. Pop. (1921) 15,497 (town); 37,293 (commune). The cathedral of S. Cassiano possesses interesting reliquaries, and contains the tomb of Petrus Chrysologus, archbishop of Ravenna (d. 449), a native of Imola. S. Domenico has a fine Gothic portal and S. Maria in Regola an old campanile. The town also contains some fine palaces. The communal library has some mss., including a psalter with miniatures, that once belonged to Sir Thomas More (1304). The citadel is square with round towers at the angles. Imola has two large lunatic asylums with over 1,800 inmates. The Madonna del Piratello, 2

m. outside the town to the north-west, is in the early Renaissance style (1488); the campanile was probably built from Bramante's plans in 1506.

See L. Orsini, *Imola* (Bergamo, Arti Grafiche, 1907) well illustrated.

IMP, originally a shoot of a plant or tree used for grafting (O.E. *impa*, a graft, shoot). The verb "to imp" was especially used of the grafting of feathers on to the wing of a falcon or hawk to replace broken plumage, and is frequently used metaphorically. Like "scion," "imp" was, till the 17th century, used of a member of a family, especially of high rank, hence often used as equivalent to "child."

IMPALA, a South African antelope. See **PALLA**.

IMPATIENS, in botany, a genus (family Balsaminaceae) of annual or biennial herbs, sometimes becoming shrubby, comprising some 350 or more species, chiefly natives of the mountains of tropical Asia and Africa, but also found widely distributed in the north temperate zone and in South Africa. The flowers, which are purple, yellow, pink or white and often showy, are spurred and irregular in form and borne in the leaf-axils. The name is derived from the fact that the seed-pod when ripe discharges the seeds by the elastic separation and coiling of the valves. *Impatiens Noli-tangere*, touch-me-not, an annual succulent herb with yellow flowers, is probably wild in moist mountainous districts in north Wales, Lancashire and Westmorland. *I. Roylei*, a tall hardy succulent annual with rose-purple flowers, a Himalayan species, is common in England as a self-sown garden plant or garden escape. In North America there are five native species, of which the spotted touch-me-not or jewel-weed (*I. biflora*), with orange-yellow flowers, mottled with brown, and the pale touch-me-not or jewel-weed (*I. pallida*), with pale yellow flowers, are widely distributed across the continent. *I. Balsamina*, the common balsam of gardens, a well-known annual, is a native of India; it is one of the showiest of summer and autumn flowers and of comparatively easy cultivation. *I. Sultani*, a handsome plant, with scarlet flowers, a native of Zanzibar, is easily grown in a greenhouse throughout the summer, but requires warmth in winter.

IMPEACHMENT, the English form of judicial parliamentary procedure against criminals, in which the House of Commons are the prosecutors and the House of Lords the judges. It differs from bills of attainder (*q.v.*) in being strictly judicial. When the House of Commons has accepted a motion for impeachment, the mover is ordered to proceed to the bar of the House of Lords, and there impeach the accused "in the name of the House of Commons, and of all the Commons of the United Kingdom." The charges are formulated in articles, to each of which the accused may deliver a written answer. The Commons appoint managers to conduct the prosecution, but the whole House in committee attends the trial. The defendant may appear by counsel. The president of the House of Lords is the lord high steward in the case of peers impeached for high treason; in other cases the lord chancellor. The hearing takes place as in an ordinary trial, the defence being allowed to call witnesses if necessary, and the prosecution having a right of reply. At the end of the case the president "puts to each peer, beginning with the junior baron, the questions upon the first article, whether the accused be guilty of the crimes charged therein. Each article is proceeded with separately in the same manner, the lord high steward giving his own opinion the last" (May's *Parliamentary Practice*, c. xxiii.). Should the accused be found guilty, judgment follows if the Commons move for it, but not otherwise. The Commons thus retain the power of pardon in their own hands, and this right they have in several cases expressly claimed by resolution, declaring that it is not parliamentary for their lordships to give judgment "until the same be first demanded by this House." Spiritual peers occupy an anomalous position in the trial of peers, as not being themselves ennobled in blood; it is customary for them to withdraw before judgment is given, entering a protest "saving to themselves and their successors all such rights in judicature as they have by law, and by right ought to have." An impeachment, unlike other parliamentary proceedings, is not interrupted by prorogation, nor even by dissolution. Proceedings in the House of Commons preliminary to an impeachment are sub-

ject to the ordinary rules, and in the Warren Hastings case an act was passed to prevent the preliminary proceedings from discontinuance by prorogation and dissolution. A royal pardon cannot be pleaded in bar of an impeachment, though it is within the royal prerogative to pardon after the lords have pronounced judgment. The point was raised in the case of the earl of Danby in 1679, and the rule was finally settled by the Act of Settlement. Persons found guilty on impeachment may be reprieved or pardoned like other convicts. Impeachment will lie against all kinds of crimes and misdemeanours, and against offenders of all ranks. In the case of Simon de Beresford, tried before the House of Lords in 1330, the House declared "that the judgment be not drawn into example or consequence in time to come, whereby the said peers may be charged hereafter to judge others than their peers," from which Blackstone and others have inferred that "a commoner cannot be impeached before the Lords for any capital offence, but only for high misdemeanours." In the case of Edward Fitzharris in 1681, the House of Commons in answer to a resolution of the Lords suspending the impeachment, declared it to be their undoubted right "to impeach any peer or commoner for treason or any other crime or misdemeanour." And the House of Lords has in practice recognized the right of the Commons to impeach whomsoever they will. The procedure has, however, been reserved for great political offenders whom the ordinary powers of the law might fail to reach. It has now fallen into desuetude. The last impeachments were those of Warren Hastings (1788-1795) and Lord Melville (1806), but an unsuccessful attempt was made by Thomas C. Anstey to impeach Lord Palmerston in 1848.

United States.—In the United States the procedure of impeachment both in the national and in almost all of the state governments is very similar to that described above. The national constitution prescribes that the House of Representatives "shall have the sole power of impeachment" and that "the Senate shall have the sole power to try all impeachments." The House appoints managers to conduct the prosecution at the bar of the Senate, and the vote of the Senate is taken by putting the question separately to each member, who, during the trial, must be on oath or affirmation. In ordinary cases the president or president *pro tempore* of the Senate presides, but when the president of the United States is on trial the presiding officer must be the chief justice of the United States Supreme Court. A two-thirds vote is necessary for conviction. The president, vice-president or any civil officer of the United States may be impeached for "treason, bribery or other high crimes and misdemeanours," and if convicted, is removed from office and may be disqualified for holding any office under the government in future. The officer after removal is also "liable and subject to indictment, trial, judgment and punishment, according to law." The term "civil officers of the United States" has been construed as being inapplicable to members of the Senate and the House of Representatives. The president's pardoning power does not extend to officers convicted, on impeachment, of offences against the United States. Since the organization of the Federal government there have been only nine impeachment trials before the United States Senate, and of these only two resulted in convictions. The two most famous cases are those of Justice Samuel Chase of the United States Supreme Court in 1805, and of President Andrew Johnson, in 1868.

See English constitutional histories generally (Maitland etc.); also, for U.S.A., W. A. E. Strich "20 Cases and Comment 454," etc. *Harvard Law Review*, 684 etc.

IMPERIA, a city of Liguria, Italy, the capital of the province of Imperia, on the coast of the Ligurian Sea, 46 m. by rail east of Nice and 70 m. south-west of Genoa, 115 ft. above sea-level. Pop. (1921) 15,497 (town), 25,013 (commune). It consists of a picturesque old town on the heights and a modern town of villas on the lower slopes. The principal church is a large structure of 1780 with dome rebuilt in 1821. A few remains of the old city walls may be seen. About 2 m. to the north-east on the same bay is Oneglia, with a fine church, S. Giovanni Battista, designed by Gaetano Amoretti, a hospital (1785) and a large prison. It suffered considerably from the earthquake of 1887. Both have small but safe harbours, both are frequented for sea-bathing, and

both are embowered amid olive groves; and the district is famous for the quality of its oil.

Imperia, formerly Porto Maurizio, appears as *Portus Maurici* in the Maritime Itinerary. After being subject to the marquises of Turin (11th century) and of Clavesana, it was sold by Boniface of Clavesana in 1288 to Genoa in return for a yearly payment; in 1354 it became the seat of the Genoese vicar of the western Riviera, and thenceforth shared the fortunes of Genoa.

IMPERIAL CHAMBER (*Reichskammergericht*), the supreme judicial court of the Holy Roman empire, during the period between 1495 and the dissolution of the empire in 1806. From the early middle ages there had been a supreme court of justice for the empire—the *Hofgericht*, in which the emperor himself presided and a body of assessors found the judgments. The *Hofgericht* was connected with the person of the emperor; it ceased to act when he was abroad; it died with his death. Upon him it depended for its efficiency; and when, in the 15th century, the emperor ceased to command respect, his court lost the confidence of his subjects, and after 1450 it ceased to sit. Its place was taken by the *Kammergericht*, which appeared side by side with the *Hofgericht* from 1415, and after 1450 replaced it altogether. The king (or his deputy) still presided in the *Kammergericht* and it was still his personal court; but the members of the new "chamber" were all officials—the *consiliarii* of the imperial *aula* or *Kammer*, whence the name of the court). It was generally the legal members of the council who sat in the *Kammergericht* (see under AULIC COUNCIL); and as they were generally doctors of civil law, the court which they composed tended to act according to that law, and thus contributed to the "reception" of Roman law into Germany towards the end of the 15th century. Even the *Kammergericht*, however, fell into disuse in the later years of the reign of Frederick III.; and the creation of a new and efficient court became a matter of pressing necessity, and was one of the most urgent of the reforms which were mooted in the reign of Maximilian I.

This new court was eventually created in 1495; and it bore the name of *Reichskammergericht*, or Imperial Chamber. It was distinguished from the old *Kammergericht* by the essential fact that it was not the personal court of the emperor, but the official court of the empire (or Reich—whence its name). The emperor appointed the president; the empire nominated the rest of the judges. There were originally 16 judges (afterwards, as a rule, 18): half of these were to be doctors of Roman law, and half were to be knights; but after 1555 it became necessary that the latter should be learned in Roman law, even if they had not actually taken their doctorate.

Thus the empire at last was possessed of a court, a court resting on the enactment of the diet, and not on the emperor's will; a court paid by the empire, and not by the emperor; a court resident in a fixed place (until 1693, Spire, and afterwards, from 1693 to 1806, Wetzlar), and not attached to the emperor's person. The great result which in the issue it served to achieve was the final "reception" of Roman law as the common law of Germany. That the Imperial Chamber should itself administer Roman law was an inevitable result of its composition; and it was equally inevitable that the composition and procedure of the supreme imperial court should be imitated in the various States which composed the empire, and that Roman law should thus become the local, as it was already the central, law of the land.

The province of the Imperial Chamber, as it came to be gradually defined by statute and use, extended to breaches of the public peace, cases of arbitrary restraint or imprisonment, pleas which concerned the treasury, violations of the emperor's decrees or of laws passed by the diet, and a variety of other matters. It had also cognizance in cases of refusal to do justice, and it acted as a court of appeal from territorial courts in civil and, to a small extent, in criminal cases; but it had no authority in territories which enjoyed a *privilegium de non appellando* (such as, e.g., the territories of the electors). The business of the court was, however, badly done. Delay was interminable, thanks, in large measure, to want of funds, which prevented the maintenance of a proper number of judges. In all its business it suffered

from the competition of the Aulic Council; for that body, having lost all executive competence after the 16th century, had also devoted itself to judicial work. Composed of the personal advisers of the emperor, the Aulic Council did justice on his behalf (the erection of a court to do justice for the empire having left the emperor still possessed of the right to do justice for himself through his *consiliarii*); and it may thus be said to be the descendant of the old Kammergericht. The competition between the Aulic Council and the Imperial Chamber was finally regulated by the treaty of Westphalia, which laid it down that the court which first dealt with a case should alone have competence to pursue it.

See J. N. Harpprecht, *Staatsarchiv des Reichskammergerichts* (1757-85); G. Stobbe, *Reichshofgericht und Reichskammergericht* (Leipzig, 1878); R. Schröder, *Lehrbuch der deutschen Rechtsgeschichte* (Leipzig, 1904). (E. B.)

IMPERIAL CHEMICAL INDUSTRIES LIMITED.

This British joint stock company, which has an authorized share capital of £65,000,000, came into being through a discussion on board the "Aquitania" in Oct. 1926 between Sir Alfred Mond and Sir Harry McGowan, the chairmen respectively of Brunner Mond and Co., Ltd., and Nobel Industries, Ltd. A merger of the British chemical and allied industries within two months was the result. A brief account follows of the participating companies and their productions.

Brunner Mond and Co., Ltd.—The history of this group dates back to the partnership of John Brunner and Ludwig Mond in 1872 to manufacture alkali by the Solvay ammonia soda process. The small works begun at Winnington in 1874 made such progress that a company was formed in 1881 whose capital had been increased from time to time until (1926) it stood at £15,000,000. In 1924 the output was 32 times that of 1881.

United Alkali Co., Ltd.—The alkali industry was established in Great Britain in 1823. Its founder, James Muspratt, seized the opportunity afforded by the repeal of the salt tax to exploit the chemical process invented by the French scientist, Nicolas Le Blanc. After 1875 the production of alkali exceeded the world demand, and prices fell. This coupled with the introduction of the ammonia soda process by Brunner Mond in 1881 caused all the older works to close down. It was out of the situation so created that the United Alkali company was formed in 1890 by the chief Le Blanc process manufacturers.

British Dyestuffs Corporation, Ltd.—The synthetic dyestuffs industry in Britain had its origin in the discovery of aniline mauve by W. H. Perkin in 1856, but through lack of research in the United Kingdom the potentialities of the discovery were not realized, and Germany developed it into one of the greatest undertakings in the world. In the United Kingdom the industry was kept alive with varying degrees of vigour by Levinstein, Read Holliday and company and Claus and company. Through Claus and company the British Dyestuffs corporation can trace its descent from Brooke, Simpson and Spiller, who bought, in 1874, the firm of Perkin and sons, the first synthetic dyestuffs manufacturers.

Read Holliday and company of Huddersfield were founded as chemical manufacturers in 1830, and in 1860 they began to manufacture intermediate products and dyes. Levinstein (founded in 1865 by Ivan Levinstein) and Read Holliday and company at the outbreak of the war were manufacturing a number of dyestuffs from raw materials and many others from intermediates purchased abroad. In 1917 Levinstein, Ltd., took over the indigo works at Ellesmere Port built by Messrs. Meister, Lucius and Bruning, and synthetic indigo is produced there on a large scale. Levinstein, Ltd., purchased Claus and company in 1917. Read Holliday and company had been reorganized with Government assistance, and given the name of British Dyes, Ltd., in 1915. In 1918 British Dyes amalgamated with Levinstein under the style of the British Dyestuffs corporation. A controlling interest was purchased in Scottish Dyes, Ltd., by the British Dyestuffs corporation in 1926.

Nobel Industries, Limited.—This company was a fusion of the principal British makers of explosives, blackpowder, safety-fuses,

ammunition and germane products; it takes its name from Alfred Nobel, pioneer of the high explosives industry. The sales of high explosives in Great Britain alone have risen from 255 tons per annum about 30 years ago to about 15,000 tons annually for industrial purposes. (L. C. M.)

IMPERIAL CITIES or TOWNS is the usual English translation of *Reichsstädte*, an expression of frequent occurrence in German history. These were cities and towns subject to no authority except that of the emperor, or German king, in other words they were immediate; the earliest of them stood on the demesne land of their sovereign, and they often grew up around his palaces. A distinction was thus made between a *Reichsstadt* and a *Landstadt*, the latter being dependent upon some prince, not upon the emperor direct. (See COMMUNE, MEDIAEVAL.)

IMPERIAL ECONOMIC COMMITTEE. This is a British imperial body, which owes its authority to resolutions adopted at the Imperial Conference. It continues from one Imperial Conference to the next; it is constituted of members appointed by the several Governments of the British empire; it deals with subjects remitted to it by agreement among those Governments; and it addresses its reports thereon to the Governments of the empire.

The proposal to appoint such a committee received much support at the Imperial Economic Conference of 1923, but agreement on the terms of reference was only reached in 1924, when Mr. Baldwin, as prime minister, announced its appointment for the following purpose:

"To consider the possibility of improving the methods of preparing for market and marketing in the United Kingdom the food products of the overseas parts of the empire with a view to increasing the consumption of such products in the United Kingdom in preference to imports from foreign countries and to promote the interests both of producer and consumer."

In addition, the committee was to be asked to advise on the expenditure of a £1,000,000 fund which it was proposed to devote to furthering empire trade.

The first subjects remitted to the committee were meat and fruit. The general reference was understood to imply that precedence should be given in the United Kingdom market in the following order: United Kingdom produce, produce from the overseas empire, foreign produce.

The imperial economic committee first met in March 1925 and, by the next meeting of the Imperial Conference in 1926, had issued four reports. The Imperial Conference endorsed the work so far done, and in continuing the committee till the next Imperial Conference extended the scope of its operations thus:

"(i.) to complete the series of investigations into the marketing of empire foodstuffs in Great Britain, and, while this work is proceeding,

(ii.) to put forward for the consideration of the various Governments concerned (a) a list of raw materials for possible further marketing enquiries, and (b) suggestions for the preparation and circulation of brief preliminary surveys, as suggested by the general economic sub-committee of the Conference of any branch of empire trade and marketing, such preliminary surveys, if the Governments concerned so desire, to be followed up by further enquiries."

The committee consists of a chairman and representatives nominated by the various Governments of the empire as follows: Four by the United Kingdom, two by each dominion, two by India, one by Southern Rhodesia and two by the secretary of State for the Colonies.

In its first or general report the committee stated the case for voluntary preference, that the consumption of empire produce could be stimulated by education and publicity, by increased facilities for indicating the country of origin on goods exposed for sale, and by sustained research, scientific and economic, into specific disabilities under which empire produce might labour. It, however, emphasized that such a policy would fail without supplies, adequate and regular in quantity, of the quality desired by consumers, and sold at competitive prices.

The development of such a policy demanded executive action

beyond the scope of a committee appointed for advisory purposes, and the committee recommended that so far as the United Kingdom was concerned such executive work should be entrusted to an executive commission financed out of the proposed new fund and responsible to parliament through a minister of the Crown. This recommendation was accepted. The task was entrusted to the secretary of State for the colonies, assisted by a body known as the Empire Marketing Board (*q.v.*). The relationship between the imperial economic committee and the Empire Marketing Board is close, yet the two bodies differ radically in functions and in constitution.

In its various reports numerous recommendations unconnected with voluntary preference have been made. These cover trade practices and scientific research, and are directed to securing larger and better supplies of empire products under strictly competitive conditions. By March 1928 eight reports had been issued. Two of these—the first report already referred to and the eighth setting forth the functions and work of the committee—are of a general character, the remaining six deal with meat, fruit, dairy produce, fish, poultry and eggs and honey. The Governments of the empire have directed the committee to conduct similar enquiries into tobacco, pig products, timber and hides and skins, and to prepare preliminary trade surveys of agricultural machinery and rubber goods. The committee was engaged on this work throughout 1928. (D. C.)

IMPERIAL PREFERENCE. This consists in the charging, by States belonging to the British empire, of lower import duties on goods coming from another State of the empire than on like goods coming from countries outside the empire, or in exempting empire goods from duty altogether.

Until after the middle of the 19th century, colonial products enjoyed a preference in the customs tariff of Great Britain, and British goods in the tariffs of the colonies. Preferences in both directions disappeared about the same time. But while Great Britain removed tariff restrictions equally from all imports, from whatever source, the colonies—now obtaining responsible government, and looking upon customs as the only available source of public revenue—proceeded to impose equal duties on all imports, from whatever source. The British Government in vain protested in 1859 against the imposition of duties by Canada on British goods. The Government of Canada insisted on “the right of the people of Canada to decide for themselves both as to the mode and extent to which taxation shall be imposed.” The principle of tariff autonomy was henceforward acquiesced in by the British Government and acted upon by the self-governing colonies.

This was the situation for almost 40 years, in the course of which colonial tariffs became distinctly heavier. So great, however, was the reliance in Great Britain on the most favoured nation clause in her commercial treaties with European countries, that by her treaty with Belgium in 1862 and with the German Zollverein in 1865 she actually bound her colonies, without consulting them, to grant as favourable treatment to the products of the treaty country as to those of the mother country; *i.e.*, to grant no preference to Britain.

Changed Sentiment.—A new stage in intra-imperial trade relations was opened in 1897. In that year Canada granted tariff concessions to all countries treating her on equally favourable terms. In effect this was a preference to British goods; and in 1898 the Canadian Tariff Act was converted from one of general reciprocity to one avowedly of British preference. The Imperial Government had already in 1897 given notice to terminate the treaties with Belgium and the Zollverein.

In 1902 the policy of Canada became the policy of the dominions. At the colonial conference of that year in London the following resolution was passed:—

“That . . . it is desirable that those colonies which have not already adopted such a policy should, as far as their circumstances permit, give substantial preferential treatment to the products and manufactures of the United Kingdom. That the prime ministers of the colonies respectfully urge on His Majesty’s Government the expediency of granting in the United Kingdom preferential treatment to the products and manufactures of the colonies,

either by exemption from or reduction of duties now or hereafter imposed.”

Effect was given to this resolution by New Zealand and South Africa in 1903 and by Australia in 1906.

Tariff Reform.—Meanwhile in England the re-imposition for revenue purposes in 1902 of the old registration duty of one shilling a quarter on imported wheat had raised hopes of preference in Canada which were defeated by the abolition of the duty next year. The episode completed the conversion of Joseph Chamberlain to the principle of preference; and imperial preference was a prominent element in the policy of “tariff reform” which he laid before the country in 1903. The movement, however, failed at the time to receive sufficient popular support in Great Britain. At the next colonial conference in 1907, though the resolutions of 1902 were re-affirmed by the colonial representatives, the British Government put in a definite reservation that they could not assent in so far as the resolutions implied that it was necessary or expedient that the fiscal system of the United Kingdom should be altered.

Progress During the War.—The World War and the generous support which the dominions gave the mother country had considerable effect on public sentiment in Great Britain. Early in 1917 the important committee appointed by the Government to consider commercial policy after the war (presided over by Lord Balfour of Burleigh) recommended:—

“That His Majesty’s Government should now declare their adherence to the principle that preference should be accorded to the products and manufactures of the British overseas dominions in respect of any customs duties now or hereafter to be imposed on imports into the United Kingdom.”

A few weeks later the Imperial War Conference expressed itself in favour of “the principle that each part of the empire, having due regard to the interests of our allies, shall give specially favourable treatment and facilities to the produce and manufactures of other parts of the empire”: a resolution now passed unanimously by the representatives no longer of the dominions alone but also of Great Britain. In April 1917 Lloyd George and Bonar Law, on behalf of the Coalition Government, announced their acceptance of the principle of preference, making it clear that this did not involve the taxation of food. In Sept. 1918 the British Government withdrew from the Brussels sugar convention on the express ground that they had “now approved the principle of giving preference to empire sugar.” And, finally, in the Finance Act, introduced by Austen Chamberlain as chancellor of the exchequer in April 1919, preferential rebates on imports from the colonies or exemption from surtax were granted on practically all articles dutiable under the existing tariff.

The range of dutiable articles had been increased under stress of war. For many years before 1915 the only duties imposed by Britain were either purely for revenue purposes—those on tea, cocoa, coffee, sugar and tobacco; or for revenue with a certain mixture of ethical motive—those on wines and spirits. But the Finance Act of 1915 had introduced duties also on certain manufactured goods (the “McKenna duties”)—cinema films, clocks and watches, motor-cars and musical instruments. These were intended as luxury taxes, but had some protective effect. On these the measure of 1919 was now able to give preference.

Post-War Changes.—The area of preference was still further enlarged by the Safeguarding of Industries Act in 1921. Part I of this act provided for the imposition of duties on certain articles produced by “key industries.” The list included cameras and optical lenses and a large number of scientific instruments and apparatus, chemicals and special appliances, deemed essential for the safety of the empire; and from these duties empire goods were entirely exempted.

The growth of manufactures in Canada had affected the situation by enlarging the possibility of advantageous preference in Great Britain beyond the primary foodstuffs; motor-cars are an example. A similar extension of possibilities from Australia was brought about by the growth of fruit farming, largely as the result of the settlement on the land of ex-soldiers. The British Government took the opportunity of the imperial conference of 1923

to announce its readiness to enlarge the existing preference on dried fruits, to increase the rebate on empire tobacco and on certain wines, and to take other action of a similar character. Before these promises could be fulfilled, the Baldwin Government fell from power. The MacDonald Ministry which followed declined to carry out the intentions of its predecessors; abolished the McKenna duties; and, though it did not entirely throw over preference in revenue duties, so reduced the tax on sugar, tea and dried fruits as to make the preference of less value.

Preferences Granted by Britain.—On the return to office of Baldwin at the end of 1924, the McKenna duties were restored with the accompanying preferences; and the preference on dried fruits, tobacco, wines and sugar was increased. The range of preference was further widened in two directions. The new Safeguarding of Industries (Customs Duties) Act, 1925, imposed duties on imported cutlery, gloves and incandescent mantles; while the budget of that year introduced duties on silk, natural and artificial. To each of these new duties, empire preference was attached, amounting to one-third of the full duty in the case of the safeguarding duties, and to one-sixth in the case of silk.

By the Finance Act, 1925, the preference on sugar was stabilized at a fixed money value per cwt. for ten years or for so long within that period as the full rate of duty amounts to that figure: if the full rate falls below that figure, empire sugar is to be free of duty. By the Finance Act, 1926, all existing preferences (and that on packing and wrapping paper imposed by that act) were similarly stabilized for ten years from July 1, 1926.

Since the first grant of preference to the mother country by the great dominions, changes have from time to time taken place both in the general rates of duty and in the extent of the preference. In 1923 Canada, having in mind the removal of certain restrictions on the importation of cattle into the British market, undertook to give a discount of 10% on existing duties on British goods coming through Canadian ports. Australia increased its preference to British goods in 1920, and gave assistance to British trade both by anti-dumping legislation and by measures with respect to dyes. In 1927 the New Zealand tariff gave increased empire preference. So, during the last two decades a whole complex of preferences has grown up between the several dominions and colonies, many of them the result of definite treaties, and thus preference within the British commonwealth of nations has already become a considerable factor in the economic and political world situation. (See also **TARIFF**.)

BIBLIOGRAPHY.—The least partisan and most complete history of the whole movement down to 1921 will be found in a *Report on colonial tariff policies (1922)*, prepared for the U.S. tariff commission. Much information as to the views of the dominions and as to the volume of trade affected is given in the *Record of Proceedings of the imperial economic conference of 1923* (Cmd. 2009, 1924). The nature and extent of the preferences accorded to Great Britain, down to March 1925, together with the conditions governing the concessions, will be found in the *Survey of Overseas Markets (1925)* by the committee on industry and trade appointed by the British Government in 1924. That committee reported that "while it is difficult to obtain any exact statistical measure of the benefit to British trade of the preferential treatment, the surveys of British dominion markets and the statistics of distribution of British trade leave no room for doubt that the advantage has been substantial." (W. A.)

IMPERIAL TOBACCO COMPANY LIMITED. This British combine, the full title of which is The Imperial Tobacco Company (of Great Britain and Ireland), Limited, was formed in 1901 to incorporate a number of the leading British tobacco manufacturers, including W. D. and H. O. Wills, Lambert and Butler, John Player and Sons, W. and F. Faulkner, and Ogdens, and 13 other firms and companies. Between them, these firms control 27 factories, producing cigarettes, pipe tobaccos, cigars and snuff.

In 1928 the issued share capital of the company amounted to £42,800,000, upon which the stock markets place a heavy premium. The branches of the company cover a very large area, and it manufactures not only the tobacco sold, but the packing materials. The combine has some 20 factories engaged in the various processes of typographical and colour printing. There is also a factory devoted to the extraction of nicotine from tobacco waste. The total area of the combine's factories and warehouses in the

United Kingdom alone exceeds 5,000,000 square feet.

The work of the company extends to many places outside the United Kingdom, there being 35 factories abroad. These foreign factories do not produce manufactured goods, but are concerned only in the handling of natural tobacco and in drying and packing it for shipment to the United Kingdom. The combine employs 40,000 people. (L. C. M.)

IMPERIAL VALLEY, a depressed area in Imperial county, California, and extending into the Mexican territory of Lower California. It is approximately 110 m. long by 40 m. wide, and constitutes a part of what is known as the Colorado desert. That the valley was formed by constructional depression rather than erosion is shown by the fact that the greater part of its area is below sea-level (the bed of Salton Sink being 287 ft. below). The soil is chiefly silt deposited in the inland sea made by the Colorado delta, but in some places there is a large admixture of sand. The climate of the region is known for extremes, the daily range of temperature often exceeding 59° F. The extremes of temperature range from 125° to a minimum of 24°, although the average for the year is 71°. The annual rainfall varies from 1.5 to 3 inches.

Prior to 1893, when the California Development company was organized for the purpose of securing and delivering water to irrigate and reclaim the Imperial valley, the region was waterless, barren and uninhabited. The first water was brought into the valley with the Imperial canal (45 m. long), which curved below the international boundary into Mexico, in March 1902. Difficulties occasioned by the silting up of the California intake led to the opening of new intakes in Lower California in 1903 and 1904. Insufficient control gates allowed the Colorado river to widen the third intake during 1905-06 until its waters poured through the valley into Salton Sink. The situation became so alarming that President Roosevelt called on the Southern Pacific railway to assist in controlling the flood, and as a result the breach was closed on Nov. 7, 1906. High water soon caused another break and by Dec. 7, 1906 the entire flow of the river was again going back to Salton Sink, but this break was finally closed on Feb. 11, 1907. Levees were subsequently built to protect the region from further flood dangers. The main canal, over 50 m. in length, brought in a water-supply which, in 1919, irrigated 415,304 ac. and was capable of watering an additional 42,500 acres. The chief crops are alfalfa, cotton, cantaloupes, watermelons, asparagus, vegetables for winter markets, grapes and fruits. Cotton is the chief crop on the Mexican side of the border. The population of Imperial county increased from 13,591 in 1910 to 43,453 in 1920, or a gain of 219.7%. According to local estimates made in 1928 the population then exceeded 60,000. The chief centres of population are Calexico, El Centro, Brawley, Imperial and Holtville.

IMPEY, SIR ELIJAH (1732-1809), chief justice of Bengal, was born on June 13, 1732, and educated at Westminster with Warren Hastings, who was his intimate friend throughout life. In 1773 he was appointed the first chief justice of the new supreme court at Calcutta, and in 1775 presided at the trial of Nuncomar (*q.v.*) for forgery, with which his name has been chiefly connected in history. His impeachment was unsuccessfully attempted in the House of Commons in 1787, and he is accused by Macaulay of conspiring with Hastings to commit a judicial murder.

See E. B. Impey, *Sir Elijah Impey (1846)*; and Sir James Stephen, *The Story of Nuncomar and the Impeachment of Sir Elijah Impey (1885)*.

IMPLEMENT, a term used in the plural of weapons and tools, and hence of the necessary outfit of a trade. In its original Latin sense of "filling up" the term survives in Scots law, meaning full performance of or "fulfilment of" a contract or agreement; "to implement" is thus, in Scots law, to carry out, perform.

IMPLUVIUM, in the classic Roman house, the basin, or depressed portion of the floor in the centre of the atrium (*q.v.*) immediately beneath the compluvium or hole in the roof. It was generally of marble, and drained to a cistern.

IMPORT DUTIES: see **CUSTOM DUTIES**.

IMPORTING: IN PRACTICE. Imports can be divided into those sent forward "on consignment" and those arriving "against orders."

In either case the British importer's duty is to superintend the reception, clearance and delivery of goods, either on his own behalf or in the service of a principal. He must receive and negotiate certain documents, and prepare others. His duties fall under three heads: those required of him by (1) the government (as represented by the Board of Trade and the Customs officials); (2) the shipowner in whose vessel the goods have been carried; (3) the port authority or wharf owners responsible for berthing the vessel and (perhaps) landing the goods.

Customs Formalities.—The government requires accurate records of all goods that enter or leave the country. The importer has to complete a *Customs Entry* giving full particulars of his goods and of the importing vessel. Net quantities must be given, and the value required is the c.i.f. value or, if goods are consigned for sale, the latest sale value. Importers may by law be called upon to verify their entries and are liable to penalties for inaccuracies.

Duty-free goods are entered on a form which must be lodged at the Custom House. One copy of this form (termed the "bill") is kept by the officials and a second copy (the "warrant") is sent to the examining officer at the place where the vessel is discharging so that the goods can be compared with the owner's statement. The third copy, or "duplicate warrant" is returned to the importer.

If imported goods are dutiable (and the Customs tariff is the source of information as to what goods are dutiable) three courses are open to the importer. (a) By paying duty forthwith, the goods may be cleared for removal as soon as required: or, to postpone payment of duty, storage may be arranged either (b) at the port of importation, or (c) elsewhere, subject to H.M. Customs approval. In the former case a form is prepared and presented at the Custom House. Should an importer wish to defer payment of duty he can have goods stored in a bonded warehouse by special arrangement. When it is desired to remove goods from a bonded warehouse into consumption the entry formalities are completed by the preparation of a warehouse warrant of the appropriate kind, and the payment of duty.

Goods of Empire origin entitled to enter the country at the preferential rates of duty, have to be vouched for by a certificate of origin bearing the signature of the British consul at the port of shipment or place of production. This certificate, with such further evidence by way of invoices, bills of lading, etc., as may be specially required, must be tendered when the entry is lodged at the Custom House. If a claim to preference cannot at once be substantiated, the goods can be secured by depositing duty at the full rate pending production of satisfactory evidence.

British returned goods which, but for their British origin, would be dutiable, are entered by bill of store in addition to the appropriate entry form. Supporting commercial documents must also be produced. This procedure only holds when goods are re-imported within five years of exportation.

Special forms govern the entry of goods by *bill of sight* (in the absence of proper details for an entry), by *baggage sufferance* (passengers' baggage and household effects of a miscellaneous nature), statutory declaration for plate imported for private use, key industry entry (for goods subject to ad valorem duty under the Safeguarding of Industries act, 1921) and goods which may be intended to qualify for drawback upon re-export.

Satisfying the Shipowner.—The shipowner's chief anxiety is to get his vessel discharged promptly and to secure payment of his *freight* charge, if not prepaid. The importer will have received from his shipper, either direct or through a bank, a set of *Bills of Lading* which, on being presented to the shipowner properly endorsed, will substantiate the importer's claim to the goods. The inward freight clerk in the shipowner's office, to whom the bills must be presented, will satisfy himself as to the validity of the endorsement, check the details of the goods as shown by the bill of lading with those furnished on his *manifest* (i.e., the list of cargo prepared at the starting port by the ship's representatives)

and as to the payment, or security for, the freight charge, and will then grant a *freight release* or *ship's delivery order*.

In the temporary absence of bills of lading, some shipowners will permit delivery of goods when the importer has signed and lodged a *banker's guarantee*. Other lines allow delivery overside to craft to commence upon the lodgment of a provisional release, so long as the craft is not moved away from the ship until the proper *release* has been obtained and presented.

The Dock or Wharf.—Before removing goods one must also satisfy the dock or wharf officials that delivery is being made to the rightful owner, and must also pay or guarantee their charges. For this purpose the bill of lading, properly endorsed and released, or the equivalent documents (freight release, provisional release, or ship's delivery order) must be produced at the dock office, as must the customs entry unless clearance from customs has already been arranged. An applicant other than the original importer of goods will need to be provided with a transfer order, delivery order or sub-order, or possibly several such, showing between them a correct chain of instructions from the original importer to the actual applicant. (J. A. D.)

UNITED STATES

Consular Invoice.—The initial requirement for the importation of merchandise into the United States, if valued over \$100, is the presentation of an invoice for certification, to the U.S. Consular officer for the district in which the merchandise was manufactured or purchased. This must show the time when, the place where, the person by whom and the person to whom the merchandise is sold or agreed to be sold; or if secured otherwise than by purchase, the place from which shipped, the time when and the person to whom and the person by whom shipped; and other necessary information. Such invoice to be signed by the seller or shipper, or the agent of either. One copy of the certified invoice, which is made in triplicate, or in quadruplicate for merchandise intended for immediate transportation, is forwarded with the bill of lading to the consignee in the United States.

Entry.—Upon the arrival of merchandise the consignee is required to prepare and present an entry at the Customs House within 48 hours. Entry may be made for immediate consumption, warehouse or for immediate transportation without appraisement to another port. After the entry is lodged, a preliminary estimate of the duties based upon the statements contained in the entry, is made and the amount of duty thus ascertained is paid by the importer and a permit is issued to him, which releases the merchandise with the exception of the packages designated for examination by the appraiser. The appraiser is the officer authorized by law to ascertain the dutiable value of imported merchandise for the guidance of the collector in assessing and collecting the correct amount of duty of ad valorem merchandise. He may advance the entered value of merchandise to a point representing, in his opinion, the market value in the country from which the merchandise is shipped. He also describes the merchandise in order that the collector may determine the final rate to be applied. The surveyor of customs weighs, gauges and measures merchandise subject to specific rates of duty before delivering to the importer; and, in the case of goods entered for warehouse, before the transfer to the designated to a bonded warehouse. A report is made to the collector as a basis for the final assessment of duty in liquidation.

Warehousing.—If the importer desires the merchandise may remain in a bonded warehouse designated by the importer for a period not exceeding three years from date of importation without payment of duty. All goods with the exception of perishable or dangerous articles or those free of duty may be stored in a bonded warehouse. Any time during the three year period the importer may withdraw any portion of the merchandise, not less than an entire package, and pay the duty upon such portion withdrawn. Merchandise imported for which no entry is made is sent to a General Order warehouse, which is under the jurisdiction of the collector, where it may remain for one year, during which time the importer may claim it and make proper entry. There are also certain requirements of the Department of Agriculture with regard to the importation of meats, food products and drugs, which

the collector of customs is required to enforce before delivery and samples of these articles are required for examination and analysis. There are also similar requirements with regard to the importation of plants, grains and fruits from particular countries.

Passengers' Baggage.—The foregoing procedure relates to merchandise. For articles brought into the United States by passengers in their baggage a declaration form is distributed by the steamship employees to the passengers upon the return voyage. This form covers all articles acquired abroad by gift, purchase or otherwise. *Returning residents* of the United States are permitted to bring in free of duty articles up to but not exceeding \$100 acquired abroad for personal or household use, or as souvenirs, if not intended for sale or purchased on commission for other persons. All *Non-residents* of the United States will be treated for customs purposes as non-residents and are entitled to bring in free of duty all personal effects, without limitation as to value, which were actually owned by them and in their possession abroad at the time of or prior to their departure from a foreign country, which are necessary and proper for their wear and use, provided they are not intended for other persons or for sale. The dutiable effects are appraised by customs officers and duty, if any, estimated and paid to the collector's representative upon the pier.

Liquidation.—The appraiser, after examination of the merchandise, returns the properly completed invoice to the collector who thereupon determines the proper paragraph of the schedules of the dutiable or free list applicable to the particular articles in question, and thereupon the amount of duty is ascertained. The collector's liquidation of entries of merchandise, subject to a specific duty, is also based upon the report of the surveyor. A notice of additional duty or refund is sent to the importer for the final adjustment of the account—if the liquidation results in an amount different from that found at the time of the preliminary estimate and payment of duty when entry was made.

Customs Court.—A customs court is provided for a review of questions of classification when the importer is dissatisfied with the collector's decision; also for a review of the dutiable value of imported merchandise as determined by the U.S. appraiser. The decisions of the U.S. customs court with regard to questions of law and classification are also reviewable by the U.S. court of customs appeals.

Provisionally Free Merchandise.—There are many classes of merchandise which upon submission of the required proof may be admitted without payment of duty. There are also provisions for the importation of many articles under bond for a limited period in accordance with regulations prescribed by the secretary of the Treasury. (H. C. S.)

IMPORTS. A term used to describe the commodities brought into a country by the operations of commerce. Considered economically, the imports into a country represent payments for services rendered by the importing country. These services may have taken the form of (1) the exportation of goods; (2) services, such as the services of ships, or commercial or financial commissions; or (3) interest on capital previously exported by the importing country. After the World War, another source of imports arose out of the payment of indemnities, Germany being compelled to export to the Allies and thus causing them to receive imports. The repayment of the inter-allied debts set up a cause of imports, consisting of exports made by one ally to another. (See TRADE.)

The difference between the imports and exports of a country, as recorded by its customs houses, is called the "balance of trade" (see BALANCE OF TRADE). The records made at the custom house can refer, of course, only to material commodities, but a country may at any time be importing services, the value of which cannot and is not recorded in the trade returns. To such imported services the term "invisible imports" is sometimes applied.

The values at which imports are officially recorded by customs houses varies with different nations; in the case of the United Kingdom, the imports are entered at what are called c.i.f., values, that is, values representing the cost, insurance and freight; or when goods are consigned to the United Kingdom for sale, at the latest sale value of such goods. (See also EXPORTS.)

IMPORTS, INVISIBLE: see BALANCE OF TRADE.

IMPOSITION, in ecclesiastical usage, the "laying on" of hands by a bishop at the services of confirmation and ordination as a sign of a spiritual gift or conferring special service (Lat. *imponere*, to place or lay upon). The word is also used of the levying of a burdensome or unfair tax or duty, and of a penalty; also a trick or deception. In the printing trade the term is used of the arrangement of pages of type in the "forme."

IMPOST, a tax or tribute, and particularly a duty levied on imported or exported merchandise. In architecture, a moulding, series of mouldings, projecting band, carved ornament or projecting block, marking the spring of an arch, and placed at the top of the pier or section of wall that carries the arch. In Byzantine work the block sometimes placed between the capital of a column and the arches which it carries is known as an impost block.

IMPOTENCE: see NULLITY OF MARRIAGE.

IMPRESARIO (Ital.), literally one who undertakes any kind of venture or enterprise (*cf.* *emprise*); hence more specifically one who promotes and manages musical and other entertainments—operas, concerts and so forth. *Entrepreneur* has the same meaning.

IMPRESSIONISM. In music, impressionism has been adopted as a term for compositions of a type analogous to impressionist paintings, in which the outlines are blurred and the expression of a mood or the suggestion of a scene, rather than the purely musical development and treatment of his material, has been the principal aim of the composer. Bach's Chromatic Fantasia might be regarded also as impressionistic. Later, Chopin and Schumann supplied many other instances, clearly forecasting the still more highly-developed methods of Debussy, Delius and other modern practitioners, with whose music, as exemplified in such works as *L'Après-midi d'un Faune* of the one and *In a Summer Garden* of the other, the term has been more especially identified.

IMPRESSIONISM, a term applied to certain anti-academic and anti-romantic tendencies in late 19th century painting, advocated and carried into effect by Edouard Manet, Claude Monet, Auguste Renoir, Camille Pissarro, Edgar Degas, and a number of lesser men who followed the example set by these leaders. Originally the word Impressionism was coined by a journalist as a term for opprobrium in a derisive criticism of a painting by Claude Monet, called "Impressions," the actual subject of which was a sunset. This work was shown in 1863 in a special room known as the *Salon des Refusés*, together with many other paintings by artists who, like Monet, had suffered from the uncompromising hostility of the Salon jury to all originality and experimental enterprise, and who had risen in revolt against the placid self-righteous attitude of the French official Salon. The opening of the Salon des Refusés was due to the direct initiative of the emperor Napoleon III.

As a matter of fact, unlike the English Pre-Raphaelites, who deliberately banded together, chose the name for their association, and formulated a set of theories and a programme, the so-called "Impressionists" of the '60s were a number of individual artists thrown together by force of circumstance, and held together by their spirit of revolt against the tyranny of the school.

If there is any general aim to be traced through the various manifestations that have become known as Impressionism, it is the substitution in art of transitory appearance for permanent fact. The Impressionist paints things as they appear at any given moment and not as they actually are according to his knowledge of their permanent form and colour. Thus, if the contour of a figure or object happens to be obliterated or blurred by shadow or distance, he will render the undefined masses of shadow or the blurred silhouette as they are reflected on his retina, and not endeavour to give them the definition which his knowledge tells him lies hidden beneath the momentary appearance. In the same way he will record the modifications of colour caused by intervening atmosphere and by reflection. Green foliage appears blue in the distance, shadows are not neutral greys or browns, but partake of and are modified by the colours of the surroundings; a ridge of mountains against a light sky does not appear as a sharp silhouette, but an interchange of rays produces a radiating zone

connecting the light and dark masses; the rays of the sun on a clear day, setting behind a tree or a hill, seem to eat into the forms behind which the fiery orb is sinking; and, above all, there is in nature a vibrant movement of light, for the rendering of which the Impressionists have tried to develop an adequate formula.

The research work of the scientists Helmholtz and Chevreul, establishing the wave movement of light and sound and the theories of the solar spectrum happened to coincide with the Impressionist experiments and, no doubt, contributed towards the Impressionist technique of "divisionism" or "vibrism," as it came to be called in its later and more scientific phase. It is quite likely that the influence of the scientists upon Monet, the originator of the Impressionist technique, has been overrated, since the beginnings of divisionism can be traced to Watteau and Chardin and Turner. Indeed, there is no question that Monet, who paid repeated and lengthy visits to England, was as deeply impressed by Turner's achievement, as Delacroix, a generation earlier, had been by Constable's, and that he followed his natural impulse rather than scientific theory.

The technique of Impressionism followed the doctrine that colour, as a definite quantity, does not exist, but is only the result of the play of light upon form. Even shadows are deemed to be, not the negation of light, but an altered form of it. By the rigid exclusion from the palette of all but the actual colours contained in the spectrum, and the placing of dabs of alternating colours upon the canvas, instead of mixing the required tones upon the palette, the Impressionists invested their paintings with a degree of luminosity and with a vibrant quality suggestive of atmospheric vibration that had not previously been obtained by any other method. Light thus became the real subject of pictorial art, and anything was deemed worthy of representation so long as it afforded an opportunity for recording the effect of light upon nature. Thus Monet painted his famous series of "Hay-ricks," noting the appearance of a hay-stack at different hours of the day and in varying conditions of light, changing the canvas from hour to hour, to take it up again when the conditions happened to be identical. In this pursuit of light and atmospheric vibration, substance was in danger of being altogether sacrificed to surface appearance, and design was not always given due attention, although the Impressionists were by no means as haphazard in their manner of composition as they were accused of being by their detractors.

Parallel with this technical innovation came the Impressionists' revolt, led by Manet, against the academic canons of beauty. It was inspired by passionate interest in actuality, that is to say in contemporary life and manners, and was closely akin to the literary movement led by Flaubert, the Goncourts and Zola. Now that the Impressionist battle, which at the time aroused so much bitterness, belongs to past history and can be viewed in right perspective, it is quite clear that the alleged revolutionaries of the '60s and '70s were in reality the champions of the best tradition, and that their art was deeply rooted in the art of the past.

Manet.—The eclectic imitators of types that have become acknowledged standards of excellence are not the upholders of tradition: their art spells decadence. The revolutionary line passes through those who, having assimilated the tradition of the past, continue to build upon it and to bring it into harmony with the age in which they live. But Manet's generation, shocked by the artist's departure from the letter, failed to recognize that he had maintained the spirit of tradition in painting an "Olympia" which was in the direct line of descent, through Velazquez's "Venus with the Mirror" and Goya's "Maja desnuda," from Giorgione's and Titian's "Reclining Venus." The picture, now in the Louvre, caused as furious a storm of indignation as the same artist's "Déjeuner sur l'herbe," which his revilers claimed to be painted in defiance of all principles of design—a charge that would scarcely have been brought against the artist, had his revilers known that the design was practically traced, line by line, from a Marcantonio engraving after a painting of "Neptune and Nymphs" by Raphael.

Degas.—Degas, although his technique had little or nothing in

common with Impressionism, is generally classed with that group, because he was linked with them by the tie of friendship, took part in their exhibitions, and shared with them their keen interest in contemporary life. It was his love of actuality, of the momentary impression, that made him discard all conventional methods of composition and gave his pictures frequently an air of the accidental and unpremeditated, somewhat like a snapshot photograph. Yet behind this apparent neglect of rule lies a highly developed sense of balanced arrangement and rhythmic flow of compositional line; for Degas, too, had made a profound study of the old masters, and devoted much time to copying the primitives. His draughtsmanship, in particular, has a classical perfection rivalled only by Ingres.

Renoir.—Renoir, who connects the art of his time with the French 18th century, adopted for a lengthy period the Impressionist technique and vision, but later in life abandoned the search after the visual truth of ephemeral effects in favour of a more permanent plasticity of form, achieved by the concentration of light on projections and of shade on recessions—a kind of modelling by means of an arbitrarily placed source of illumination for which Nature offers no parallel.

Pissaro, Sisley, Whistler and Sickert.—Less personal, though of considerable distinction, was the contribution made to the movement by Camille Pissaro and Alfred Sisley. The minor adherents to Impressionism need not here be recorded. By the close of the 19th century, Impressionism had fought through to recognition not only in France, but had gained adherence and changed the entire current of art throughout Europe. Whistler was connected with the movement from its very birth. Wilson Steer and Walter Sickert, by their example, spread the new artistic gospel in England, Leibermann and Kuehl in Germany, Segantini in Italy, Van Rysselberghe and Claus in Belgium, Sorolla in Spain, Thaulow and Krøyer in Scandinavia; whilst among the American painters Sargent, Harrison and Alexander were profoundly influenced by the movement.

Impressionism may be regarded as the final chapter in the gradual conquest of representational truth, which began with Giotto's vitalization by Byzantine rigidity, and proceeded step by step through the discovery of the law of perspective by the 15th century Florentines, the use of light and shade for the suggestion of relief by Leonardo da Vinci, the application of colour as an integral part of pictorial structure by the great Venetians, and the accurate registration of tone values by Velazquez. With Impressionism this search for truthful representation of appearances had reached a point where further advance in the same direction had become impossible. Painters had succeeded in capturing the most transient effects of surface glitter and tremulous atmosphere and, in the doing, had come dangerously near to losing their grip on form and substance.

The futility of any attempt to carry the Impressionist principles beyond the stage reached by the great initiators is demonstrated by the Neo-Impressionists, or pointillists, Signac and Seurat, who tried to give a scientific basis to Monet's system of divisionism by the mechanical use of rounded dabs of pure colours of equal size, divided by regular intervals of pure white. Theoretically, these dabs of spectral colours were intended to blend into luminous tones of the desired intensity when viewed from the right distance. In reality, they remained isolated dabs of colour, and the pictures thus produced bore an exasperatingly mechanical aspect.

Seurat, however, soon abandoned his rigid adherence to this method and adopted a less pronounced style of pointillism. His great importance in the history of 19th century art lies, however, in his practical protest against the disintegration of form which was the natural consequence of Monet's innovation. His later work marks a return to expressive pattern and sculptural form, and bears witness to the profundity of his outlook and to his ability to combine with his mosaic-like treatment a respect for orderly rhythm and solid volumes. Seurat thus became one of the chief connecting links between Impressionism and the modern tendencies which are embraced in the term "Post-Impressionism." (See POST-IMPRESSIONISM, PAINTING.)

FRENCH, AMERICAN, AND SPANISH IMPRESSIONISTS

1. "Le Pont de Courbevoie," by Georges-Pierre Seurat (1859-91), French; one of the connecting links between Impressionism and Post-Impressionism. The Seine, one of Seurat's favourite subjects, is here painted in Pointillist manner, with rounded dabs of colour divided at regular intervals by pure white. 2. "Olympia," by Edouard Manet (1833-83), French leader of that revolt against academic canons of beauty which later came to be called Impressionism. This picture, now in the Louvre, raised a storm of protest in academic art circles when first exhibited in 1865. As a transition work, it is a landmark in the evolution of French art. 3. "Vue de Landres (effet de neige)," by Camille Pissarro (1830-1903), French, one of the most notable exponents of Impressionism. Pissarro's landscapes illustrate his ability to blend Classicism and Impressionism. 4. "Nocturne, Blue and Silver, Battersea Reach," by James A. McNeill Whistler (1834-

1903), an American painter who lived in England, and was connected with Impressionism from its birth. His "Nocturnes" (painted about 1877) usually represented moonlight effects on water, with lights on the banks shining through mists. These studies in subtle colour and atmosphere aroused furious criticism at first, but eventually exerted a strong influence on the world of modern painting. 5. "Lavacourt," a landscape by Claude Monet (1840-1926), French. Monet was the originator of the technique which, because of its emphasis upon the transitory appearance rather than the permanent quality of objects, was dubbed "Impressionism" by academic critics. 6. "Tunny fishing on the waterfront of Ayamonte," by Joaquín Sorolla y Bastida (1862-1923), Spanish; one of a series of fourteen mural paintings in the Hispanic Museum, New York, representing the provincial life of Spain and showing a broad impressionistic technique.

IMPRESSMENT, the name given in English to the exercise of the authority of the State to "press" or compel the service of the subject for the defence of the realm. Every sovereign State must claim and at times exercise this power. All the monarchical, or republican Governments of Europe have employed the press at one time or another. All forms of conscription, including the English ballot for the militia, are based on this sovereign right. In England impressment may be looked upon as an erratic, and often oppressive, way of enforcing the common obligation to serve in "the host" or in the *posse comitatus* (power of the county). In Scotland, where the feudal organization was very complete in the Lowlands, and the tribal organization no less complete in the Highlands, and where the State was weak, impressment was originally little known. After the union of the two parliaments in 1707, no distinction was made between the two divisions of Great Britain. In England the kings of the Plantagenet dynasty caused Welshmen to be pressed by the lords marchers, and Irish kerns to be pressed by the lords deputy, for their wars in France. Complaints were made by parliament of the oppressive use of this power as early as the reign of Edward III., but it continued to be exercised. A small sum called *imprest-money*, or coat and conduct money, was given to the men when pressed to enable them to reach the appointed rendezvous. Soldiers were secured in this way by Queen Elizabeth, by Charles I. and by the parliament itself in the Civil War. The famous New Model Army of Cromwell was largely raised by impressment. Parliament ordered the various county committees to select recruits of "years meet for their employment and well clothed." After the revolution of 1688 parliament occasionally made use of this resource. In 1779 a general press of all rogues and vagabonds in London to be drafted into the regiments was ordered. It is said that all who were not too lame to run away or too destitute to bribe the parish constable were swept into the net. As they were encouraged to desert by the undisguised connivance of the officers and men who were disgusted with their company, no further attempt to use the press for the army was made.

The impressment of sailors was regarded as a prerogative of the Crown. From an act of Philip and Mary (1556) it appears that the watermen of the Thames claimed exemption from the press as a privileged body. They were declared liable, and the liability was clearly meant to extend to service as a soldier on shore. In the fifth year of Elizabeth (1563) an act was passed to define the liability of the sailors. It is known as "an act touching politick considerations for the maintenance of the navy." By its term all fishermen and mariners were protected from being compelled "to serve as any soldiers upon the land or upon the sea, otherwise than as a mariner, except it shall be to serve under any captain of some ship or vessel, for landing to do some special exploit which mariners have been used to do." The operation of the act was limited to ten years, but it was renewed repeatedly, and was at last indefinitely prolonged in the 16th year of the reign of Charles I. (1631). The justices of the peace in the coast districts, who were often themselves concerned in the shipping trade, were not always zealous in enforcing the press. The pressed sailors often deserted with the "imprest money" given them. Loud complaints were made by the naval officers of the bad quality of the men sent up to serve in the king's ships. On the other hand, the press gangs were accused of extorting money, and of making illegal arrests. In the reign of Queen Anne (1703) an act gave parish authorities power to apprentice boys to the sea, and exempted such apprentices from the press for three years, and until the age of 18. It especially reaffirmed the part of the Vagrancy Act of 1597 which left rogues and vagabonds subject to be pressed for the sea service. By the act of 1740, all men over 55 were exempted from the press, together with lads under 18, foreigners serving in British ships (always numerous in war time), and landmen who had gone to sea during their first two years. The act for "the better supplying of the cities of London

and Westminster with fish" gave exemption to all masters of fishing-boats, to four apprentices and one mariner to each boat, and all landmen for two years, except in case of actual invasion.

Subject to such limitations as these, all seafaring men, and watermen on rivers, were liable to be pressed between the ages of 18 and 55, and might be pressed repeatedly for so long as their liability lasted. The rogue and vagabond element were at the mercy of the justices of the peace. The frightful epidemics of fever which desolated the navy till late in the 18th century were largely due to the infection brought by the prisoners drafted from the ill-kept jails of the time. Even merchant ships were stopped at sea and the sailors taken out. On one occasion, in 1802, an East Indiaman on her way home was deprived of so many of her crew by a man of war in the Bay of Biscay that she was unable to resist a small French privateer, and was carried off as a prize with a valuable cargo. In 1795 it was found necessary to impose on the counties the obligation to provide "a quota" of men, at their own expense. The local authorities provided the recruits by offering high bounties, often to debtors confined in the prisons. These desperate men were a very bad element in the navy. In 1797 they combined with the United Irishmen, of whom large numbers had been drafted into the fleet as vagabonds, to give a very dangerous political character to the mutinies at the Nore and in the south of Ireland. The pressing of sailors alleged to be British from American vessels was one of the causes of the war between Great Britain and the United States in 1812. After the conclusion of the great Napoleonic wars in 1815 the power of the press was not again exercised. In 1835 an act was passed during Sir James Graham's tenure of office as first lord of the admiralty, by which men who had once been pressed and had served for a period of five years were to be exempt from impressment in future. Sir James, however, emphatically reaffirmed the right of the Crown to impress seamen. The introduction of engagements for a term of five years in 1853, and then of long service produced so large a body of voluntary recruits, and service in the navy became so popular, that the question had no longer any interest save an historical one. But in the World War compulsory service, both in the navy and army, once more became necessary and was enforced under the Military Service Acts of 1915 and 1916.

BIBLIOGRAPHY.—For the general subject of impressment see F. Grose, *Military Antiquities* (1812), vol. ii., p. 73 *et seq.* S. R. Gardiner gives many details in his history of James I. and Charles I., and in *The Civil War* (1886-91). The acts relating to the navy are quoted in *A Collection of the Statutes relating to the Admiralty*, etc., published in 1810. Some curious information is in the papers relating to the Brest Blockade edited by John Leyland for the Navy Record Society. (D. H.)

IMPRISONMENT, as a legal term imprisonment denotes any involuntary restraint of the liberty of an individual whether he be confined within bounds, as in a jail or prison, or merely subjected to arrest and detention in his home or even in a public place. Such detention, if not warranted by law, constitutes the crime of *false imprisonment*, punishable as such and also by an action for damages prosecuted by the injured party.

As a legal process the primary object of imprisonment is to enforce obedience to an order of a court or to assure the presence of an alleged or convicted offender for questioning or for such disposition of him as may be deemed necessary, whether his indictment or trial or the execution of the judgment that may be pronounced against him. The wide range of the judicial power of commitment to prison is illustrated by the fact that in many cases not only persons under suspicion of criminal misconduct, but necessary witnesses whose presence cannot otherwise be assured, defaulting debtors and children brought into court for their protection and safe-keeping may be thus confined. It is only in recent years, little more than a century, that, with the gradual abolition of the death penalty, of branding, mutilation and other methods of corporal punishment as the usual penalties for crime, imprisonment has come, in itself, to be employed as a punishment. It is now, in the several countries of western Europe as well as in the United States, the common penalty for criminal misconduct of every description. From this point of view,

imprisonment presents itself as an important phase in the slow development of humanitarian sentiment in the Western world. But its story, as related elsewhere (*see* PRISON), creates the hope that it is not the last word in society's treatment of the offender. Certain it is that the convict prison has betrayed the humanitarian impulse to which it owes its existence.

In this latter phase of its development, imprisonment may be said to have a double object; first, that of inflicting upon the offender the suffering that he has earned by his crime and, second, that of protecting the community from further depredations by his close confinement. To secure the former of these aims the life of the prisoner was made as hard and revolting as he could endure; to secure the latter he was immured in stone or steel cells behind bars and formidable walls, in structures of the bastille type, under the constant observation of armed guards. It can be said that, upon the whole, these two objectives of penal imprisonment have been adequately secured. A third aim of the system, which has incongruously mingled with its more immediate purposes, is that of reforming the character of the prisoner. This purpose has, however, been completely defeated by the sordid and demoralizing conditions of prison life.

The principal object of prison reformers from John Howard down to the present time has been to ameliorate these conditions and the last few years have witnessed several hopeful experiments—notably that of Thomas Mott Osborne at Auburn and Sing Sing prisons in the United States—to make the term of imprisonment a period of schooling in character and citizenship. This is, indeed, the avowed aim of many if not of most of the correctional institutions for children, as well as of the State reformatories for youthful offenders in the United States and of the Borstal institutions in England. If the system of imprisonment is ultimately to justify itself, it can be only through the successful outcome of these efforts.

The period of imprisonment imposed, as a penalty for delinquency, varies from a few days in the case of commitments for trifling offences to the life of the offender in the case of wilful murder and sometimes of other crimes of the graver sort. In a few instances the penalty is definitely prescribed by law, but in all but a few cases the term to be served rests in the discretion of the court in which the judgment of conviction was given within minimum and maximum limits fixed by statute. As an incentive to good conduct on the part of the prisoner most of the American States have adopted some form of indeterminate sentence, the date of release being determined by the prison authorities or by an independent board of parole within limits prescribed by law or by the sentencing court. After such release on parole and up to the expiration of his maximum sentence the parolee is still a quasi prisoner, being at large under the supervision of the prison authorities and subject to be recalled by them to finish his term in confinement. *See* CONVICT; PAROLE; PUNISHMENT.

IMPROMPTU, a short literary composition which has not been, or is not supposed to have been, prepared beforehand, but gains its merit from the ready skill which produces it without premeditation. The word seems to have been introduced from the French language in the middle of the 17th century. Poets have, from earliest ages, made impromptus, and the very art of poetry, in its lyric form, is a modified improvisation. Many of the epigrams of the Greeks, and still more probably those of the Roman satirists, particularly Martial, were delivered on the moment, and gained a great part of their success from the evidence which they gave of rapidity of invention. But it must have been difficult then, as it has been since, to be convinced of the value of that evidence. Who is to be sure that the impromptu-writer has not, like Mascarille in *Les Précieuses ridicules*, employed his leisure in sharpening his arrows? Voltaire was celebrated for the

savage wit of his impromptus, and was himself the subject of a famous one by Young. Less well known but more extemporaneous is the couplet by the last-mentioned poet, who being asked to put something amusing in an album, and being obliged to borrow from Lord Chesterfield a pencil for the purpose, wrote:—

Accept a miracle instead of wit,—

See two dull lines with Stanhope's pencil writ.

The word "impromptu" is sometimes used to designate a short dramatic sketch, the type of which is Molière's famous *Impromptu de Versailles* (1663), a miniature comedy in prose.

In music any extemporised composition might be regarded as an impromptu, but in actual usage the name is applied only to written compositions of an indeterminate and, as it were, improvisatory character. The finest and most famous are those of Chopin, four in number.

IMPROVISATION: *see* EXTEMPORIZATION.

IMPROVISATORE (Ital. *improvvisatore*), a word for a poet who recites verses which he composes on the spur of the moment. It became recognized as an English word in the middle of the 18th century, and is used by Smollett in his *Travels* (1766). In speaking of a woman, the feminine *improvisatrice* is used.

IMPULSE, a conation or conative tendency acting by itself and apart from the whole system of motives which constitute the character of the agent. *See* VOLITION; WILL; PSYCHOLOGY, and the bibliographies given there.

INAUDI, JACQUES (1867—), Italian calculating prodigy, was born at Onorato, Piedmont, on the 15th of October, 1867. When between seven and eight years old, at which time he was employed in herding sheep, he already exhibited an extraordinary aptitude for mental calculation. His powers attracted the notice of various showmen, and he began to give exhibitions. He was carefully examined by leading French scientists, including Charcot, from the physiological, psychological and mathematical point of view. The secret of his arithmetical powers appeared to reside in his extraordinary memory, improved by continuous practice. It appeared to depend upon hearing rather than sight, more remarkable results being achieved when figures were read out than when they were written.

INBREEDING is the term used to define any system of breeding which involves the mating of relatives. It has been deliberately used by animal breeders ever since the modern breeds of livestock were created: it is the sole method of reproduction of many self-fertilised plants, e.g., beans, barley, oats and peas, and it has been used extensively by plant breeders in order to "fix" varieties of certain naturally cross-fertilised species such as maize. Exceptionally it has been practised by man, as for example in the ancient royal families of Egypt. In spite of the evidence provided by experience, however, there has been and still is great diversity of opinion concerning the average results of this system of mating. It has been shown on the one hand that inbreeding in a population in which it is not the rule commonly leads to the production of offspring which exhibit a diminution in size, lowered powers of resistance and fertility, that in fact markedly defective types appear among the progeny of an inbred strain. On the other hand it is abundantly clear that inbreeding can and does promote uniformity of type amongst the individuals exposed to its action and to an increase in prepotency when an individual of an inbred line is mated with unrelated stocks. Among plants the self-fertilised forms show no signs of being less vigorous than the normally cross-fertilised. It is not surprising therefore that a disagreement as to the effects and value of inbreeding exists. In different human societies there are to be found laws forbidding marriage save between relatives and laws forbidding the marriage of relatives altogether. Laws and practices vary because inbreeding has not always yielded the same results.

But during recent years it has been shown that the results of inbreeding, diverse as they are in different cases, can readily and consistently be explained by an appeal to the Mendelian theory. (*See* HEREDITY: *Breeds and Breeding*.) It has been demonstrated that the chief effect of inbreeding, the continued mating of close relatives, is to increase genetic purity or the proportion of homo-

zygous individuals or, conversely, to decrease heterozygosis among the progeny. To take an example; a recessive strain, such as that of dwarf peas, is crossed with a corresponding dominant strain, such as that of tall peas. All the first (filial) generation are hybrid (heterozygous) but show only the dominant character tallness. If these are allowed to become self-fertilised, $\frac{1}{4}$ of the resulting generation are pure (homozygous) dwarfs, $\frac{1}{2}$ are heterozygous tall and $\frac{1}{4}$ are homozygous tall. (See HEREDITY.) If all these plants are allowed in their turn to become self-fertilised the homozygous classes will continue to breed true while the heterozygous class will again break up into 25% homozygous dwarfs, 50% heterozygous tall and 25% homozygous tall. If self-fertilisation of all individuals is continued generation after generation, the proportion of the heterozygous individuals becomes steadily reduced (being halved in each generation) and the proportion of the homozygous types steadily increases because these remain homozygous and are augmented in each self-fertilised generation. This progressive reduction in heterozygosis (the condition of being heterozygous or hybrid for one or more Mendelian characters) occurs automatically in all Mendelian factor-pairs, regardless of the number involved. The rate of reduction is determined by the intensity of the inbreeding practised. Reduction is most rapid in cases of self-fertilisation; theoretically it is calculated that for all practical purposes complete homozygosis (the condition of being homozygous for all characters the individual exhibits) should be attained in the 10th generation in such cases. Reduction is less rapid in cases of continued brother and sister mating: it is estimated that starting with heterozygous individuals the proportion of heterozygosis after ten generations becomes reduced from 50% to about 5%. This theoretical expectation is not likely to be realised in practice for the reason that the theory requires that mating shall be at random whereas in practice there is bound to be some certain selection, either natural or artificial, and this is more likely to preserve the heterozygous than the homozygous. The matings of relatives beyond the first cousin degree reduces heterozygosis so slightly they cannot really be considered as cases of inbreeding.

In breeding practice a system of mating commonly adopted is that of using a male upon a number of his half-sisters, these being half-sisters to each other. Such a system requires five generations to reduce the proportion of heterozygosis to about half the original value. Even after fifteen generations the proportion is 8.5%, and this system, therefore, is to be commended for all general purposes in cases in which a breeder wishes to avoid the dangers of too narrow inbreeding, to preserve the advantages of inbreeding and to keep wholly within his own stock. In the case of those breeds of livestock of which a study has been made, Shorthorn cattle, for example, it has been shown that the breeders who have contributed most notably to the advancement of the breeds have been those who used the system of inbreeding. They did so in most cases because they possessed males of such superior merit as sires that they wished to perpetuate and to concentrate the blood of these. Their methods earn the endorsement of science, for if it is desired to fix a type, the best guarantee that the animals shall not only look alike but also be alike in hereditary constitution is close relationship.

Critical experimental analysis of the effects of inbreeding has shown that its action takes the form of isolating a number of types each homozygous for the characters it displays and differing one from the other in respect of hereditary constitution. If, as is often the case, some of the recessive factors carried in the original stock are deleterious in their effects, some of the homozygous lines produced by inbreeding will be weakly or even incapable of life. Others, however, will have become purified of all harmful recessives and these will continue to flourish. But even these may show some decrease in general vigour, size and fertility; by crossing the best of these inbred stocks the effects of hybrid vigour (see HYBRIDISM) can be brought into play and a purified stock of equal, or better, performance than the original will be produced.

In the case of man, as in that of his domesticated animals, consanguinity in marriage is not dangerous in itself, it is only

dangerous for the reason that human stocks are heavily laden with undesirable recessives, hidden in the heterozygous hybrid. These are most frequently revealed in the children when closely related individuals marry. Inbreeding exerts its effects solely through the medium of inheritance and not through the blood-relationship of the individuals concerned. Incest—inbreeding of the narrowest kind—is not harmful *per se* but only because of the recessives it may bring to light. It is usually more common among the biologically inferior: it is not surprising therefore that the offspring of such are themselves biologically unworthy, but this does not mean that incest itself is pernicious but only that it should be forbidden in the cases of unsound stock. There is no biological objection to the marriage of a man to his deceased wife's sister; there is some endorsement for the social attitude concerning the marriage of uncle and niece and of first cousins. If it can be shown that there is nothing but good in the pedigrees then cousinship is no barrier to marriage. This applies not only to first cousins but also to the case of the marriage of non-related individuals, for if in the pedigrees of such there appear records of the same disadvantageous character then on biological grounds marriage is undesirable, assuming of course that marriage implies parentage. It is because pedigrees have not been and still are not kept that in all cases of prospective marriage of related individuals it is necessary to advocate caution—it has to be assumed that *all* such marriages are fraught with danger.

INCA, a Peruvian tribe, speaking the Quichua dialect, who, at the time of the Spanish expedition under Pizarro, in 1533, exercised paramount rule over a region extending, west of the Atlantic slope of South America, between Quito in Ecuador and the River Maule in Chile. They were a highland people and organized a renaissance of the earlier "civilization," characterized by megalithic, polygonal structures of stone, which appears to have prevailed in the uplands of Bolivia and Peru at an anterior date (known as the Tiahuanaco period). (See SOUTH AMERICA: *Archaeology*.) The earliest traditional records of the people are mythological. The ancestors of the tribe are supposed to have emerged from certain caverns in a hill (*Tampu-tocco*, "House of Windows"), in a region known as *Paccari-tampu* ("House of the Dawn"), under the leadership of four brothers, all bearing the title of *Ayar*. The chief was the eldest brother, named Manco, who was the high-priest of the tribal god, the Sun, whose emblem was a fetish in the form of a bird, kept concealed in a basket. This fetish possessed oracular powers, and directed the migrations of its votaries. The other brothers were named Cachi (Salt), Uchu (Pepper), and Auca (Pleasure). Their sister-wives, who bore the title of Mama ("Mother"), were named respectively, Occllo, Huaco, Cura and Raua. These eight personalities were regarded as divine in origin, being descendants of the Sun god.

Under the direction of an oracle, these leaders conducted the tribe northward in search of empire. The leader, Manco, was equipped with a golden rod, which, according to the prophecy, would sink into the ground when the predestined home was attained. In the course of the migration, the three younger brothers perished. Cachi was persuaded to return for certain fetishes which had been left behind in a sacred cave; but when he had entered the sanctuary, his escort rolled a great rock against the entrance. Uchu, in the attempt to seize a mysterious stone statue, encountered on the journey, was himself turned to stone. The locality, known in later times as Huanacauri, was one of the most sacred spots in Peru, and was the scene of the Huarachicu ceremony. (See SOUTH AMERICA: *Archaeology*.) Auca, who was winged, was asked by Manco to fly to the top of a distant hill (afterwards the site of the great Sun-temple in Cuzco), but he, on completing the feat, was transformed to stone. Nevertheless the tribe followed, the test of the golden rod was applied, and Cuzco, the seat of the later Inca empire, was founded.

Most traditions give Manco's immediate successor as Sinchi Rocca, but one account interpolates a long list of rulers between the two. It is probable that Manco is in the main a legendary character, dating back, possibly to the Tiahuanaco period. Rocca appears to have been the first ruler bearing the royal title of *Sapa Inca* (Only Inca), and it is probable that his accession heralded the epoch associated with Inca domination. In fact he may be regarded as the first Inca "historical" ruler. The evolution of the Inca tribe into a ruling caste has brought about a certain confusion in the use of the word "Inca." Originally tribal, it became a term of rank, as applied to the members of the official hierarchy (invariably members of the paramount tribe). And, at the same time, the phrase "The Inca" is commonly used in connection with the supreme ruler, regarded as a god on earth and the descendant of the old tribal god, the Sun (obviously the translation of one of his titles, *Sapa Inca*, or "Only Inca"). The development of the peculiar form of state-socialism, controlled by a bureaucracy wielding religious authority, is described in the article, SOUTH AMERICA, *Archaeology*, with an account of the stone-work, pottery, and other industrial arts as compared with those of their predecessors and their tributaries. See the bibliography appended to that article.

(T. A. J.)

INCANTATION, the use of words, spoken, sung or chanted, usually as a set formula, for the purpose of obtaining a result by their supposed magical power (Lat. *incantare*, to chant a magical formula). See MAGIC; SPELL.

INCE, WILLIAM, English 18th century furniture designer and cabinetmaker. He was one of the most successful imitators of Chippendale, although his work was lighter. It came between the massive and often florid style of Chippendale and the more boudoir-like forms of Hepplewhite. He was for many years in partnership with Thomas Mayhew, with whom he published a folio volume of 95 plates, under the title of *The Universal System of Household Furniture* (undated, but probably c. 1762).

INCE-IN-MAKERFIELD, urban district, Ince parliamentary division, Lancashire, England, adjoining the borough of Wigan. Pop. (1921) 22,855. Served by the Leeds and Liverpool canal, it contains large collieries, iron works, forges and cotton mills. The Old Hall is a beautiful example of half timbered architecture.

INCENDIARISM: see ARSON.

INCENDIARY MIXTURES are required for the destruction of buildings or material by fire. They are of two types: (1) mixtures of inflammable materials, such as pitch or resin, with oxidizing agents such as potassium nitrate, which on ignition produce much flame of long duration; (2) mixtures of the thermit type in which molten products at a very high temperature are scattered by a mild bursting charge. These mixtures contain aluminium and iron oxide, which on ignition form iron and aluminium oxide and produce a temperature of about 2,500° C.

(W. R. Ho.)

INCENSE, the perfume (fumigation) arising from certain resins and gum-resins, barks, woods, dried flowers, fruits and seeds, when burnt, and also the substances so burnt. In its literal meaning the word "incense" is one with the word "perfume," the aroma given off with the smoke (*per fumum*) of any odoriferous substance when burnt. But, in use, while the meaning of the word "perfume" has been extended so as to include everything sweet in smell, from smoking incense to the invisible fresh fragrance of fruits and exquisite scent of flowers, that of the word "incense," in all the languages of modern Europe in which it occurs, has, by an opposite process of limitation, been gradually restricted almost exclusively to frankincense. (See FRANKINCENSE.)

Probably nowhere can the actual historical progress from the primitive use of animal sacrifices to the later refinement of burning incense be more clearly traced than in the pages of the Old Testament; but in the monuments of ancient Egypt the authentic traces of the use of incense that still exist carry us back to a much earlier date. From Meroe to Memphis the commonest subject carved or painted in the interiors of the temples is that of some contemporary Pharaoh or Pharaoh worshipping the

presiding deity with oblations of gold and silver vessels, rich vestments, gems, the firstlings of the flock and herd, cakes, fruits, flowers, wine, anointing oil and incense. One of the best known of these representations is that carved on the memorial stone placed by Tethmosis (Thothmes) IV. (1533 B.C.) on the breast of the Sphinx at Gizeh. The tablet represents Tethmosis before his guardian deity, the sun-god Rê, pouring a libation of wine on one side and offering incense on the other. The ancient Egyptians used various substances as incense, but in course of time frankincense was specially consecrated to the worship of the gods.

In the authorized version of the Bible, the word "incense" translates two wholly distinct Hebrew words. In various passages in the latter portion of Isaiah (xl.-lxvi.), in Jeremiah and in Chronicles, it represents the Hebrew *lebōnah*, more usually rendered "frankincense"; elsewhere the original word is *ketoreth* (Exod. xxx. 8, 9; Lev. x. 1; Num. vii. 14, etc.), a derivative of the verb *kitter* (Pi.) or *hiktir* (Hiph.), which verb is used, not only in Exod. xxx. 7, but also in Lev. i. 9, iii. 11, ix. 13, and many other passages, to denote the process by which the "savour of satisfaction" in any burnt-offering, whether of flesh or of incense is produced. Sometimes in the authorized version (as in 1 Ki. iii. 3; 1 Sam. ii. 28) it is incorrectly made to mean the burning of incense. The expression "incense (*ketoreth*) of rams" in Ps. lxvi. 15 and the allusion in Ps. cxli. 2 ought both to be understood, most probably, of ordinary burnt-offerings. The "incense" (*ketoreth*), or "incense of sweet scents" (*ketoreth sammim*), called, in Exod. xxx. 35, "a confection after the art of the apothecary," or rather "a perfume after the art of the perfumer," which was to be regarded as most holy, and the imitation of which was prohibited under the severest penalties, was compounded of four "sweet scents" (*sammim*), namely stacte (*nataph*), onycha (*sheheleth*), galbanum (*helbenah*) and "pure" or "fine" frankincense (*lebōnah zaccab*), pounded together in equal proportions, with (perhaps) an admixture of salt (*memullah*). It was then to be "put before the testimony" in the "tent of meeting" (a transference of late ceremonial back to the years of sojourn in "the wilderness"). It was burnt on the altar of incense by the priest every morning when the lamps were trimmed in the Holy Place, and every evening when they were lighted or "set up" (Exod. xxx. 7, 8). A handful of it was also burnt once a year in the Holy of Holies by the high priest on a pan of burning coals taken from the altar of burnt-offering (Lev. xvi. 12, 13). Pure frankincense (*lebōnah*) formed part of the meat-offering (Lev. ii. 16, vi. 15), and was also presented along with the shew bread (Lev. xxiv. 7) every Sabbath day (probably on two golden saucers; see Josh. Ant. iii. 10, 7). The religious significance of the use of incense, or at least of its use in the Holy of Holies, is distinctly set forth in Lev. xvi. 12, 13.

The introduction of incense took place late in the history of the Jewish ritual (see Wellhausen, *Geschichte Israels*, i. 75 seq.); but evidently the idea that the odour of a burnt-offering (cf. the *κλίστης ἡδὺς αὐτῆς* of Od. xii. 369) is pleasing to the deity, being at least the vehicle by which the sacrifice can be successfully conveyed to its destination, was a survival of a very early belief, and underlies the biblical phrase "a savour of satisfaction" (Gen. viii. 21; Lev. i. 9 and elsewhere; cf. Eph. v. 2). It is probable that the development of a sensuous appreciation of pleasant perfumes, and knowledge of the sources from which these could be derived, expressed itself not only in domestic habits, sanitation, etc., but also in religious ceremonial, so that the custom of adding some kind of incense to animal sacrifices naturally arose. The final stage (not reached in the Levitical ritual) was the offering of incense pure and simple.

The "marbles" of Nineveh furnish frequent examples of the offering of incense to the sun-god and his consort (2 Ki. xxiii. 5). The kings of Assyria united in themselves the royal and priestly offices, and on the monuments they erected they are generally represented as offering incense and pouring out wine to the Tree of Life. According to Herodotus (i. 183), frankincense to the amount of 1,000 talents' weight was offered every year, during the feast of Bel, on the great altar of his temple in Babylon.

The monuments of Persepolis and the coins of the Sassanians

show that the religious use of incense was as common in ancient Persia as in Babylonia and Assyria. Five times a day the priests of the Persians (Zoroastrians) burnt incense on their sacred fire altars. Herodotus (iii. 97) states that the Arabs brought every year to Darius as tribute 1,000 talents of frankincense. The Parsees still preserve in western India the pure tradition of the ritual of incense as followed by their race from probably the most ancient times.

The *Ramayana* and *Mahabharata* afford evidence of the employment of incense by the Hindus, in the worship of the gods and the burning of the dead, from the remotest antiquity. Its use was obviously continued by the Buddhists during the prevalence of their religion in India, for it is still used by them in Nepal, Tibet, Ceylon, Burma, China and Japan. These countries all received Buddhism from India, and a large proportion of the porcelain and earthenware articles imported from China and Japan into Europe consists of innumerable forms of censers. The Jains all over India burn sticks of incense before their Jina. The commonest incense in ancient India was probably frankincense. The Indian frankincense tree is found chiefly where the Buddhist religion prevailed in ancient times, in Bihar and along the foot of the Himalayas and in western India, where it particularly flourishes in the neighbourhood of the Buddhist caves at Ajanta. Now, however, the incense in commonest use in India is benzoin. But the consumption of all manner of odoriferous resins, gum resins, roots, woods, dried leaves, flowers, fruits and seeds in India, in social as well as religious observances, is enormous. The incense sticks and pastils made at the Mohammedan city of Bijapur in the Mahratta country are celebrated all over western India.

As to the *thūa* mentioned in Homer (*Il.* ix. 499, and elsewhere) and in Hesiod (*Works and Days*, 338), there is some uncertainty whether they were incense offerings at all, and if so, whether they were ever offered alone, and not always in conjunction with animal sacrifices. That the domestic use, however, of the fragrant wood *thūon* (*Arbor vitae*) was known in the Homeric age, is shown by the case of Calypso (*Od.* v. 60), and the very similarity of the word *thūon* to *thūos* may be taken as almost conclusively proving that by that time the same wood was also employed for religious purposes. It is not probable that the sweet-smelling gums and resins of the countries of the Indian ocean began to be introduced into Greece before the 8th or 7th century B.C., and doubtless *λίβανος* or *λίβανωρός* first became an article of extensive commerce only after the Mediterranean trade with the East had been opened up by the Egyptian king Psammetichus (c. 664–610 B.C.). The new Oriental word is frequently employed by Herodotus; and there are abundant references to the use of the thing among the writers of the golden age of Attic literature (see, for example, Aristophanes, *Plut.* i. 114; *Frogs*, 871, 888; *Clouds*, 426; *Wasps*, 96, 861). Frankincense, however, though the most common, never became the only kind of incense offered to the gods among the Greeks. Thus the Orphic hymns are careful to specify, in connection with the several deities celebrated, a great variety of substances appropriate to the service of each; in the case of many of these the selection seems to have been determined not at all by their fragrance but by some occult considerations which it is now difficult to divine.

Among the Romans the use of religious fumigations long preceded the introduction of foreign substances for the purpose (see for example, Ovid, *Fast.* i. 337 seq., *Et non exiguo laurus adusta sono*). Latterly the use of frankincense (*mascula thura*, Virg., *Ecl.* viii. 65) became very prevalent, not only in religious ceremonies, but also on various state occasions, such as in triumphs (Ovid, *Trist.* iv. 2, 4), and also in connection with certain occurrences of domestic life. In private it was daily offered by the devout to the *Lar familiaris* (Plaut. *Aulul.* prol. 23); and in public sacrifices it was not only sprinkled on the head of the victim by the pontifex before its slaughter, and afterwards mingled with its blood, but was also thrown upon the flames over which it was roasted.

No perfectly satisfactory traces can be found of the use of incense in the ritual of the Christian Church during the first four centuries. (Compare Duchesne, *Christian Worship* [Eng., trans.,

1904], ch. ii., "The Mass in the East," v. "The Books of the Latin Rite," and xii. "The Dedication of Churches.") Its use was foreign to the synagogue services on which the worship of the primitive Christians is known to have been originally modelled; and its associations with heathen solemnities, and with the evil repute of those who were known as "thurificati," would still further militate against its employment. Various authors of the ante-Nicene period have expressed themselves as distinctly unfavourable to its religious, though not, of course, to its domestic, use. Thus Tertullian, while (*De Cor. Mil.* 10) ready to acknowledge its utility in counteracting unpleasant smells ("si me odor alicujus loci offenderit, Arabiae aliquid incendio"), is careful to say that he scorns to offer it as an accompaniment to his heartfelt prayers (*Apol.* 30; cf. 42). Athenagoras also (*Legat.* 13) gives distinct expression to his sense of the needlessness of any such ritual ("the Creator and Father of the universe does not require blood, nor smoke, nor even the sweet smell of flowers and incense"); and Arnobius (*Adv. Gent.* vii. 26) seeks to justify the Christian neglect of it by the fact, for which he vouches, that among the Romans themselves incense was unknown in the time of Numa, while the Etruscans had always continued to be strangers to it. Cyril of Jerusalem, Augustine and the Apostolic Constitutions make no reference to any such feature either in the public or private worship of the Christians of that time. But in the Apostolic Canons (can. 3), the *θυμίαμα* is spoken of as one of the requisites of the eucharistic service. It is easy to perceive how it should inevitably have come in along with the whole circle of ideas involved in such words as "temple," "altar," "priest," which about this time came to be so generally applied in ecclesiastical connections. At a later date Roman Catholic theologians treated it as symbolically typifying the prayers of the faithful and the virtues of the saints. Ultimately the word incense was sometimes used symbolically of prayer; a usage anticipated in Rev. v. 8, viii. 3, 4 (cf. Origen, *Contra Celsum*, viii. 17, 20).

Incense in the Church of England.—The Missal of the Roman Church, however, enjoins incensation before the introit, at the gospel and again at the offertory, and at the elevation, in every high mass; the use of incense also occurs at the exposition of the sacrament, at consecrations of churches and the like, in processions, in the office for the burial of the dead and at the exhibition of relics. On high festivals the altar is censured at vespers and lauds. There is reason to believe that notwithstanding the order for the use of incense at every celebration, it was used in British churches only on high festivals, and then only in rich churches down to the period of the Reformation, and that the ritual of the mass remained unchanged until the death of Henry VIII. (Jan. 28, 1547). On Whitsunday 1549 the first Prayer Book of Edward VI. came into use under the first Act of Uniformity (2 and 3 Ed. VI. ch. 1) which required its exclusive use in public worship so as to supersede all other forms of service. Another Act (3 and 4 Ed. VI. ch. 10) required the old service books to be delivered up to be destroyed. The first Prayer Book does not contain any direction to use or any mention of incense. It is a controverted question whether incense did or did not continue to be in ceremonial use under the first Prayer Book or during the rest of Edward VI.'s reign. No evidence has hitherto been discovered which justifies us in answering this question in the affirmative. The second Prayer Book of Edward VI. (1552), published under the authority of the second Act of Uniformity (5 and 6 Ed. VI. ch. 1), contains no reference to incense. Edward VI. died July 6, 1553. Queen Mary by statute (1 Mary, sess. 2, ch. 2) abolished the Prayer Book, repealed the Acts of Uniformity and restored "divine service and administration of sacraments as were most commonly used in England in the last year of Henry VIII." The ceremonial use of incense thus became again an undoubted part of the communion service in the Church of England. A proclamation issued (Dec. 6, 1553) directed the churchwardens to obtain the proper ornaments for the churches; and the bishops in their visitations inquired whether censers had been furnished for use. Mary died Nov. 17, 1558. On June 24, 1559, the second Prayer Book of Edward VI. (with a few alterations having no reference to incense) was again established, under the

authority of the third Act of Uniformity (1 Eliz. ch. 2), as the exclusive service book for public service. There is no evidence of the ceremonial use of incense under Elizabeth's Prayer Book, or under the present Prayer Book of 1662 (established by the fourth Act of Uniformity, 13 and 14 Charles II., ch. 4) until the middle of the 19th century; and there is no doubt that as a ceremony of divine worship, whether at the Holy Communion or at other services, it was entirely disused. There are a good many instances recorded of what has been called a fumigatory use of frankincense in churches, but this use of incense—which was utilitarian and not symbolical—must be carefully distinguished from its ceremonial use. In the general revival of Church ceremonial which accompanied and followed the Oxford Movement incense was not forgotten, and its ceremonial use in the pre-Reformation method has been adopted in a number of churches since 1850. Its use has been condemned as an illegal ceremony by the ecclesiastical courts. In 1868 Sir Robert Phillimore (Dean of the Arches) pronounced the ceremonial use of incense to be illegal in the suit of *Martin v. Mackonochie* (2 A. and E.L.R. 116). The case was carried to the Privy Council on appeal, but there was no appeal on the question of incense. Again, in 1870, the ceremonial use of incense was condemned by Sir Robert Phillimore in the suit of *Sumner v. Wix* (3 A. and E.L.R. 58).

Notwithstanding these decisions, it was insisted by those who defended the revival of the ceremonial use of incense that it was a legal custom of the Church of England. The question was once more elaborately argued in May 1899 before an informal tribunal consisting of the archbishop of Canterbury (Dr. Temple) and the archbishop of York (Dr. Maclagan), at Lambeth Palace. On July 31, 1899, the archbishops decided that the liturgical use of incense was illegal. The Lambeth "opinion," as it was called, failed to convince the clergy against whom it was directed any better than the judgments of the ecclesiastical courts, but at first a considerable degree of obedience to the archbishops' view was shown. Various expedients were adopted, as, e.g., the use of incense just before the beginning of service, by which it was sought to retain incense without infringing the law as laid down by the archbishops. There remained, nevertheless, a tendency on the part of the clergy who used incense, or desired to do so, to revert to the position they occupied before the Lambeth hearing—that is, to insist on the ceremonial use of incense as a part of the Catholic practice of the Church of England which it is the duty of the clergy to maintain, notwithstanding the decisions of ecclesiastical judges or the opinions of archbishops to the contrary.

"Incense," in Hastings, *Encyclopaedia of Religion and Ethics* (with many refs.); E. G. Atchley, *History of the Use of Incense in Divine Worship* (1909). See also **PERFUMES**.

INCENSE CEDAR (*Libocedrus decurrens*), a handsome North American tree of the pine family (Pinaceae), called also white cedar, native to high mountains from Oregon and Nevada to Lower California. It is a valuable timber tree, with cinnamon-red bark, frequently attaining a height of 150 ft., and sometimes a trunk diameter of 7 feet. The slender branches, with much flattened branchlets and lustrous, cypress-like leaves, form a beautiful crown. The soft, durable, straight-grained, fragrant, resinous wood is utilized for fence posts, telephone poles and lumber. The incense cedar is planted for ornament, as is also the smaller South American species (*L. chilensis*). Besides the foregoing, six other species of incense cedar are found, one each in Chile, New Caledonia, China and Japan, and two in New Zealand. Of these, *L. tetragona*, of Chile, and *L. Doniana*, of New Zealand, are valuable timber trees.

INCEST, sexual intercourse between persons so related by kindred or affinity that legal marriage cannot take place between them (see **MARRIAGE**, especially the section *Canon Law*). In England incest formerly was not generally treated as a crime, although, along with other offences against morals, it was made punishable by death in 1650. Since the Restoration it had, to use Blackstone's phrase, been left to the "feeble coercion of the spiritual courts," but bills to make it a criminal offence have at various

times been unsuccessfully introduced in parliament. In 1908, however, an act (The Punishment of Incest Act 1908) was passed, under which sexual intercourse of a male with his grand-daughter, daughter, sister or mother is made punishable with penal servitude for not less than 3 or more than 7 years, or with imprisonment for not more than 2 years with or without hard labour. It is immaterial that the sexual intercourse was had with the consent of the female; indeed, by s. 2 a female who consents is on conviction liable to the same punishment as the male. The act also makes an attempt to commit the offence of incest a misdemeanor, punishable by imprisonment for not more than two years with or without hard labour. The terms "brother" and "sister" include half-brother and half-sister, whether the relationship is or is not traced through lawful wedlock. Formerly all proceedings under the act were held *in camera* (s. 5), but this provision was repealed by the Criminal Law Amendment Act 1922. In *Rex v. Ball* (22 Cx, C.C. 366) it was held by the House of Lords that evidence of previous intercourse was admissible to establish guilty passion and rebut innocent association. In the law of Scotland, it was, until the Criminal Procedure (Scotland) Act 1887, a crime nominally punishable with death, but the penalty usually inflicted was penal servitude for life. This sentence was actually pronounced on a man in 1855. In the United States incest, though not an indictable offence at common law, has, generally speaking, been made a felony by statute and punishable by fine or imprisonment or both. It is also a punishable offence in some European countries, notably Germany, Austria and Italy. (W. DE B. H.)

INCH, the twelfth part of a linear foot (O.Eng. *ynce* from Lat. *uncia*, a twelfth part; see **OUNCE** and **AS**). As a measure of rainfall an "inch of rain" is equivalent to a fall of a gallon of water spread over a surface of about 2 sq. ft., or 100 tons to an acre.

INCHBALD, ELIZABETH (1753–1821), English novelist, playwright and actress, was born on Oct. 15, 1753, the daughter of a farmer, Joseph Simpson. She left home in April 1772 to seek her fortune on the London stage; two months later she married Joseph Inchbald, an actor, and in September made her début at Bristol as Cordelia to his Lear. In the next seven years she played with him in the provinces, taking important leading parts. Elizabeth Inchbald had great beauty, but was debarred from rising to the top of her profession by an impediment in her speech. After her husband's death she continued to appear on the stage until 1789, producing at the same time many adaptations of plays, and writing some farces of her own. Among her most successful adaptations were *Wives as They Were and Maids as They Are* (1797). But her fame rests on the two novels: *A Simple Story* (1791) and *Nature and Art* (1796), which have become standard works and cannot be neglected by any student of the 18th century novel.

See J. Boaden, *Memoirs of Mrs. Inchbald* (2 vols., 1833); Fanny Kemble, *Records of a Girlhood* (1878); W. Bell Scott, preface to *A Simple Story* (1880); S. R. Littlewood, *Elizabeth Inchbald and her Circle 1753–1821* (1921).

INCHCAPE, JAMES LYLE MACKAY, 1ST EARL (1852–), British shipowner, was born at Arbroath, Forfarshire, on Sept. 11, 1852, and educated there and at Elgin. In 1874 he went to India to join the firm of Messrs. Mackinnon, Mackenzie & Company, Calcutta, of which he ultimately became senior partner; he was a member of the legislative council of the Viceroy (1891–93) and a member of the Council of India from 1897 to 1911. In 1902, consequent upon the Boxer rebellion, Mackay negotiated a commercial treaty with China. In 1911 he was raised to the peerage as Baron Inchcape of Strathnaver. As a representative of the shipping industry Inchcape took a leading part in all its affairs both during the World War and after, being president of the Chamber of Shipping of the United Kingdom (1893, 1918, 1919) and president of the Shipping Federation (1926). He served on most of the Government commissions of inquiry both in India and England. He was a member of the Geddes committee on national expenditure (1921), and chairman of the Indian retrenchment committee (1922). In 1924 he was created viscount and G.C.S.I. The positions of chairman of the

P. and O. Steam Navigation Company and director of the National Provincial Bank and Suez Canal Company were other important positions which he occupied. In 1928 Lord Inchcape lost his daughter, Miss Elsie Mackay, in an attempted trans-Atlantic flight. He was created an earl, June 3, 1929.

INCHQUIN, MURROUGH O'BRIEN, 1ST EARL OF (c. 1614–1674), Irish soldier and statesman, was the son of Dermot O'Brien, 5th Baron Inchiquin (d. 1624). He belonged to a great family which traced its descent to Brian Boromhe, king of Ireland, members of which were always to the forefront in Irish public life. The first baron of Inchiquin was another Murrough O'Brien (d. 1551) who, after having made his submission to Henry VIII., was created baron of Inchiquin and earl of Thomond in 1543. When Murrough died in November 1551 his earldom passed to his nephew Donogh, son of Conor O'Brien (d. 1539), the last independent prince of Thomond (see THOMOND, EARLS OF), leaving only his barony to be inherited by his son Dermot (d. 1557), the ancestor of the later barons of Inchiquin.

Murrough O'Brien, who became 6th baron of Inchiquin in 1624, took an active part in suppressing the Irish rebellion which broke out in 1643, and during the Civil War the English parliament made him president of Munster. Early in 1648, however, he declared for Charles I., and for about two years he sought to uphold the royalist cause in Ireland. He then emigrated. In 1654 Charles II. made him an earl. He died on Sept. 9, 1674.

His son, **WILLIAM, THE 2ND EARL** (c. 1638–1692), served under his father in France and Spain, and for six years was governor of Tangier. He was a partisan of William III. in Ireland, and in 1690 he became governor of Jamaica where he died in January 1692. In 1800 his descendant Murrough, the 5th earl (d. 1808), was created marquess of Thomond, but on the death of James, the 3rd marquess, in July 1855 both the marquessate and the earldom became extinct.

INCIDENTAL MUSIC, otherwise music designed to accompany and support the action of a spoken play or other dramatic performance. Very fine music has been written in this form, such as that of Beethoven for Goethe's *Egmont*, and Mendelssohn's famous *Midsummer Night's Dream*.

INCINERATOR: see DESTRUCTORS.

INCLEDON, CHARLES BENJAMIN (1763–1826), English singer, son of a doctor in Cornwall, was the principal English tenor of his day. He sang both in opera and in oratorio, but his chief popularity lay in his delivery of ballads, such as "Sally in our Alley," "Black-eyed Susan," "The Arethusa," and others of a similarly bold and manly type. On retiring in 1822 from the operatic stage, he travelled through the provinces with an entertainment called "The Wandering Melodist." He died at Worcester on Feb. 11, 1826.

INCLINOMETER, an instrument used for measuring the dip or inclination of the dipping needle to the horizontal (see MAGNETISM, TERRESTRIAL). Inclinerometers are of two distinct classes, viz., dip circles and induction inclinometers, often called earth inductors.

Dip Circle.—The instrument shown in the fig. is intended for the determination of total force as well as dip. With this instrument four needles are provided. Two are seen in the illustration. One of these, No. 4, held between the clips DD, is a total force needle, but we may suppose it non-existent, as it is not represented in the ordinary dip circle. In modern circles of the pattern shown, the needle is a flat lozenge-shaped piece of steel, about 9 cm. long and 0.1 cm. thick. The axle, which is made of hard steel, projects on either side of the needle, and where in contact with the agate knife-edges in which it rolls has a diameter of about 0.05 cm. The two ends of the needle are marked A and B for purposes of distinction. When in position inside the box the axle of the needle is on the axis of the vertical divided circle. The needle shown in the background of the illustration happens to be vertical. When a dip observation is being made the needle takes up the appropriate inclination, and the positions of its ends are observed with the two reading microscopes, carried by the same movable piece as the two diametrically opposite verniers. The circle is divided to 0.5°, and the vernier, divided from 0 to 30, enables

minutes of arc to be read off. The reading should always be taken with a slight swing on the needle, the adjustment being made with the tangent screw until the wire in the reading microscope seems to bisect the (small) arc of vibration. Suppose the inclination observed when the plane in which the needle swings—which is necessarily parallel to the vertical circle—is inclined at an angle α to the magnetic meridian, the observed dip, I_1 , and the true dip

DIP CIRCLE, WITH TOTAL FORCE NEEDLES, FOR MEASURING (A) THE INCLINATION OF THE EARTH'S MAGNETIC FIELD TO THE HORIZONTAL AND (B) THE TOTAL FORCE

I in the magnetic meridian are connected by the relation $\cot I_1 = \cos \alpha \cot I$. If then I_2 be the dip obtained when observing in a plane perpendicular to the first one, we similarly get $\cot I_2 = \sin \alpha \cot I$. Hence for all values of α , i.e., for any pair of orthogonal planes, we have $\cot^2 I = \cot^2 I_1 + \cot^2 I_2$.

It follows that no plane can give a smaller dip than the magnetic meridian, and in the plane perpendicular to the meridian the dip is 90°, i.e., the needle is vertical. Circumstances may arise in which observing out of the meridian in two perpendicular planes has advantages but the usual practice is to observe only in the meridian. The meridian is sometimes obtained with the aid of an auxiliary compass needle, but it is usually determined by means of the result that the needle becomes vertical in the plane perpendicular to the meridian. The position where this occurs is read off on the horizontal circle, which is similarly divided to the vertical circle. Rotating the instrument through a right angle, as shown on the horizontal circle, we bring the vertical circle into the desired meridian, and by the use of a stop, not shown in the figure, can recover this position when desired. Rotating the instrument backwards 180° from this position we again bring the vertical circle into the magnetic meridian, and secure the recovery of this position by a second stop. At a fixed observatory one determination of the magnetic meridian may serve for months.

A satisfactory dip observation involves a number of readings. Calling the flat surface of the needle bearing the letters A and B

the face, and that side of the box containing the needle which is next the vertical circle the face of the instrument, we take the following readings with *A* dipping, at least two readings being taken of each end:

Instrument facing east, face of needle to face of instrument									
"	"	west,	"	"	"	"	"	"	"
"	"	west,	"	"	"	"	back,	"	"
"	"	east,	"	"	"	"	"	"	"

We then repeat these observations with *B* dipping, the reversal of the magnetization of the needle having been effected with the aid of bar magnets or a coil. The object of the reversal is to eliminate the effects of a possible gravitating couple due to the C.G. of the needle not coinciding with its axle. The object of reading both ends of the needle is to eliminate any error of centring. The object of changing the positions of the circle and of the needle is to eliminate error in the zero graduation on the vertical circle, and departure of the magnetic axis of the needle from the straight line joining its two ends. Prior to each reading, the needle is lifted off and restored to the knife-edge by a lifter, actuated by the knot *I*. It is well to do this several times before actually taking a reading. If the position of equilibrium about which the needle swings alters, or if the needle swings jerkily, its axle should be cleaned with the pith provided for the purpose. In damp weather frequent use of the pith may be necessary.

Total Force.—The needle marked 4 in the figure is stouter than the others and has a small hole in which can be screwed one of several weights provided. The total force observation consists of two experiments, both in the magnetic meridian. In the first we observe the inclination η to the horizon of needle No. 4 carrying one of its weights, and the difference μ between η and the true dip as given by an unweighted needle. In the second experiment we determine the angle μ' through which an auxiliary needle No. 3—which resembles the ordinary reversible needles Nos. 1 and 2—swinging freely on the agate edges, is deflected by No. 4 from its natural dipping position. No. 4 when deflected is in the position shown in the figure, but is protected from the observer's breath by a cover. No. 3 in its deflected position is necessarily orthogonal to No. 4, because No. 4 is so supported that its long axis is perpendicular to the line joining the lines of vision of the two reading microscopes by which the ends of No. 3 are read. There are two such deflected positions on opposite sides of the position that No. 3 would assume if undeflected. Half the difference between the two readings is taken as the deflection angle μ' . The value of the total force F is given by $F^2 = C \cos \eta / \sin \mu \sin \mu'$, where C is a constant for a particular weight, provided the distribution of magnetism in needles Nos. 3 and 4 remains unaltered. To this end these two magnets, unlike the others Nos. 1 and 2, never have their magnetism reversed. The constant C is determined from observations at a base station where F is known. In reality C varies slightly with the local value of gravity, but hardly to an extent that matters.

The dip circle can be adapted for use at sea by having the ends of the axle of the needle carried in jewelled holes. The instrument, of course, is carried on gimbals. A modification of the original sea pattern instrument, devised by Robert Were Fox, to which its inventor, Captain E. W. Creak, R.N., assigned the name of the Lloyd-Creak, has been a good deal used. To get rid of friction, a knob on the top of the box is rubbed with a corrugated ivory disc. A distance between the deflecting and deflected needles suitable for higher latitudes may be too small near the equator, where the total force is relatively small. This difficulty has been surmounted in the sea dip circles used by the Carnegie Institution by mounting the deflecting needle eccentrically in a metal box, which is attachable to the frame of the dip circle, with the side to which the deflecting needle is nearest either adjacent to or remote from the deflected needle. This gives a choice between two deflection distances.

Induction Inclinometer.—If a coil of insulated wire is spun about a diameter, an alternating current is induced unless the diameter is parallel to the lines of force of the earth's magnetic field. Hence if the axis about which the coil spins is adjusted until there is no deflection in a sensitive galvanometer, connected

to the coil through a commutator by which the alternating current is converted into direct current, then the axis must be parallel to the lines of force of the earth's field. The inclination of the axis to the horizon is then the dip. The introduction and improvement of the induction inclinometer were largely the work of H. Wild, but modifications have been subsequently made by others, especially M. Eschenhagen. Wild's form of instrument for field observations consists of a coil 10 cm. in diameter containing about 1,000 turns of silk-covered copper wire, with a resistance of about 40 ohms. The coil is pivoted inside a metal ring which can be rotated about a horizontal axle in its own plane, this axle being orthogonal to that about which the coil can rotate. Attached to the axle of the ring is a divided circle with two reading microscopes by means of which readings can be taken of the inclination of the coil's axis of rotation to the horizontal. The bearings which support the horizontal axle of the ring are mounted on a horizontal annulus, which can be rotated in a groove attached to the base of the instrument, so as to allow the adjustment of the azimuth of the axle of the ring, and hence also that of the plane in which the axis of the coil can move. The coil is rotated by means of a flexible shaft, worked by a small cranked handle and a train of gear wheels. The terminals of the coil are taken to a two-part commutator of the ordinary pattern, on which rest two copper brushes, which are connected by flexible leads to a sensitive galvanometer. The inclination of the axis of the coil can be roughly adjusted by hand by rotating the supporting ring. The final adjustment is made by means of a micrometer screw.

The first thing when making an observation is to set the azimuth circle horizontal, checking this by a striding level placed on the trunnions which carry the ring. The striding level is then placed on the axle which carries the coil, and when the bubble is at the centre of the scale the microscopes are adjusted to the zeros of the vertical circle. A box containing a long compass needle, and having two feet with inverted V's, is placed so as to rest in the axle of the coil, and the instrument is turned in azimuth until the compass needle points to a lubber line on the box. By this means the axis of the coil is brought into the magnetic meridian. The coil is then rotated, and the ring adjusted until the galvanometer needle is undeflected. The reading on the vertical circle then gives the dip. Slight faults in the adjustment are eliminated by a scheme of reversals analogous to that with the dip circle. The degree of accuracy claimed for the final value of the dip is $\pm 1'$, but a good deal depends on the judgment of the observer.

In the form of Wild inductor intended for observatory use the coil consists of a drum-wound armature, the length of which is about thrice the diameter. This armature has its axle mounted in a frame attached to the sloping side of a stone pillar, so that the axis of rotation is approximately parallel to the lines of force of the earth's field. The inclination of the axis to the magnetic meridian and to the horizontal can be adjusted by two micrometer screws. The armature is fitted with a commutator and a system of gear wheels by means of which it can be rapidly rotated. The upper end of the axle carries a plane mirror, the normal to which is adjusted parallel to the axis of rotation of the armature. A theodolite is placed on the top of the pillar, and the telescope is turned so that the image of the cross wires, seen by reflection in the mirror, coincides with the wires themselves. In this way the axis of the theodolite telescope is placed parallel to the axis of the armature, and hence the dip can be read off on the altitude scale of the theodolite.

A modified pattern of earth inductor with a suitable type of galvanometer has been devised by the department of terrestrial magnetism of the Carnegie Institution for taking dip observations at sea.

The primary object of dip observations at an observatory is to assist in determining the base value of the vertical force curves. Suppose a dip I has been observed with a dip circle or inductor at a certain time. The corresponding value of H is then derived by measuring the ordinate of the H curve, standardized by absolute measurements with the unifilar magnetometer V being simply $H \tan I$ is then known. Subtracting the force equivalent of the

corresponding ordinate of the V curve from the value thus found for V , we have the base line value. If now Δ denote a small change in a magnetic element, we easily find $\Delta I = \frac{1}{2} \sin 2I \{ (\Delta V/V) - (\Delta H/H) \}$. This shows that in high magnetic latitudes where $2I$ approaches 180° , and V is very large, a dip circle or inductor is an insensitive instrument to changes in V . It takes a very large change indeed in V to produce a change of even 0.1 in I . This has suggested the importance of devising coil instruments to measure V directly. Instruments accomplishing this in two different ways have been devised by D. la Cour of Copenhagen and D. W. Dye of the National Physical Laboratory, Teddington. The method followed by the latter is to reduce to zero the earth's vertical field by means of an artificial field produced by a current in a horizontal coil. The measurement of the current gives the strength of the artificial field, the coil constants being known, and hence the earth's vertical force.

INCLOSURE or ENCLOSURE: see COMMONS.

IN COENA DOMINI, a papal bull, so called from its opening words, first issued in 1363 and republished annually about Easter-tide. It was a statement of ecclesiastical censure against heresies, schisms, sacrilege, infringement of papal and ecclesiastical privileges, attacks on person and property, piracy, forgery and other crimes. Owing to the opposition of the sovereigns of Europe both Protestant and Catholic, who regarded the bull as an infringement of their rights, its publication was discontinued by Pope Clement XIV. in 1770. It is considered to have been formally abrogated by Pius IX. in the constitution *Apostolicae Sedis*. It received its final form from Pope Urban VIII. in 1627.

See J. Prior, art. "In Coena Domini," in the *Catholic Encyclopaedia*; M. O'Riordan, art. "Apostolicae Sedis," *ibid*.

INCOME: ECONOMIC DEFINITION. Income has been defined as:—(1) "The wealth measured in money which is at the disposal of an individual or a community, per year or other unit of time"; (2) "The inflow of satisfactions from economic goods, estimated in money" (Seligman); (3) "Those incomes which are in the form of money, including 'payments in kind.'"

These definitions have some ambiguity. In general, the term is confined to those "satisfactions which are capable of being parted with, or are usually parted with, for money." For example, the satisfaction or economic value derived from living in one's own house is commonly expressible as an annual rental, and this is usually included in income, but an analogous satisfaction from contemplating one's pictures or using one's furniture is not. Again, periodicity is essential, and a year is the common basis, though the flow may be quite uneven, in fact, and even accruing unevenly over the year. Services performed for oneself which, if performed for others, would bring in an income are not usually included, e.g., painting one's own house, or a wife's domestic services. This is extended to exclude other mutual services within a group; e.g., a club or co-operative society. There is a field of difficult distinction from capital; e.g., a series of profits from transactions which, taken singly, are regarded as capital transactions (sales of houses, lands or securities) may constitute an income in certain circumstances. And "net income" involves considerations of long period wastage in the producing agent—a coal-mine, or 99 years' lease, or a building. The term "national income" is subject to numerous special conventions.

INCOME BONDS, bonds bearing a stipulated interest rate but upon which no interest is paid unless there is sufficient income for this purpose after all other fixed charges have been met. The non-payment of interest on an income bond when the earnings are not sufficient for this purpose does not constitute a default and does not give the bondholder the right to sue. Income bonds are almost invariably brought about during reorganizations of businesses, whereupon they may be accepted by holders of old defaulted bonds or offered for sale to the general public to raise cash. Income bonds may be secured as to principal by a mortgage, in which case the mortgage would be junior to the others; or by collateral; or may be strictly of the debenture type. The interest may be either cumulative or non-cumulative. It is usually the practice to use available income to pay a portion of the interest if there is not enough to pay the full rate. Owing to the uncertainty of interest payments income bonds generally rank very low as investments and are usually regarded as just above the preferred stock of the corporation. They are often bought at a low price by unprincipled persons and sold at par or above to uninformed buyers upon the false representation that the name "income bonds" means bonds upon which an income is guaranteed, than which nothing could be further from the truth.

INCOME TAX: ECONOMIC ASPECT. The most important economic aspect of income taxation is naturally its effect upon the capacity and psychology of the taxpayer, for these may affect his willingness to work and to save, and thus have important reactions upon national production. Any general discussions about the economic effects of a particular tax are usually idle unless a comparison is made with the effects of alternative forms of taxation, designed to raise a given sum. Again, discussions of the effects of taxation in whatever form to a particular amount, are of only limited value unless the effects are brought into contrast with the effects of the expenditure of the money upon the individual and the community. It may be, for example, that the expenditure of a certain fund derived from taxation has, in its general application to the improved organization of society, an aggregate value of additional production or economic satisfaction in improved social relationships, or in peacefulness and law and order, or in industrial organization measured by an amount $2x$. Examination of the effects of the taxation to produce this sum may indicate a depressing effect upon producing agents measured by an amount x . The taxation as a whole may, therefore, yield a net profit to the community, but whereas the burden is often obvious and vocal, the benefits are generally diffused, intangible and silent, so that most discussions upon the burdens of taxation which deal only with the one side are inconclusive as a contribution to its economic aspects. But it must not be supposed that a mere quantitative surplus of benefits over burdens is a sufficient test, if the burden falls entirely upon one section and the benefits go entirely to another. Redistribution of wealth *per se* by way of taxation, lies rather beyond the field of economic science, and in that of politics. Three aspects have to be present then in discussing the economics of taxation. What is the alternative? How great is the benefit? Who gets it?

Income Tax and Prices.—With these reservations in mind, the most important economic aspect of income tax to be considered is its effect upon prices. The common business view is that an increase in income taxation tends to increase prices and vice versa. The generally accepted view of the economist is that income tax does not enter into prices. A tax on every barrel of beer enters into price, a tax upon the profits on beer does not. There is a distinction between the "incidence" of taxation and the "effects," the most recent and exhaustive examination of which was made by the Colwyn committee in their report on national debt and taxation: "In general usage the term 'incidence' covers not only the initial burden of a tax, but also the whole range of consequential effects. Economists, however, have given it a narrower meaning. For them 'incidence' is only concerned with the question on whom the more immediate burden of the tax as a tax rests. This is the first thing to be decided about any tax. It is to be distinguished from the question of further effects, which may be exceedingly important. For instance, the burden of

a tax may rest upon an employer, and in consequence he may cut down his staff; in such a case the effects of the tax may be more serious to the employees than to anyone else, but the incidence of the tax is not said to be upon them." In a full examination of the two current views, according to one of which a general income tax cannot be shifted by the person on whom it is laid, while according to the other it "can be shifted, and is in fact shifted, in the form of an addition to price," the committee concluded that "if and so far as the latter view is correct, the income tax must abandon part of its chief claim to virtue as a method of taxation. However carefully graduated, it can no longer be said to satisfy the canon of ability to pay, if the burden is indiscriminately shifted; if this happens, no one can tell how much tax he really suffers. This implication is usually not developed by those who advocate the view that income tax is added to price. They more often pursue the argument that income tax is responsible for raising prices, and is therefore a potent factor in depressing trade."

The committee's final conclusion was that the broad economic argument was true over practically the whole field and over practically the whole of the time, any exceptions being local or temporary and insufficient to invalidate it. The main feature of the doctrine is that where there is no profit there is no tax; the tax comes out of the margin of profit, and does not enter into cost. At the point at which, in economic parlance, the demand price meets the supply price, the supply price only covers costs in that part of the supply which it is just worth while to maintain. At the same time it is agreed that the "effects" as distinct from incidence of income tax, may, on balance, be repressive to production. But whether production so diminished results in a higher price level with a gold standard is a matter of rather refined economic analysis, which is not capable of ultimate solution. In the first instance there is the effect upon enterprise. One view is that a high rate of taxation lessens the willingness to work for a diminished reward, and also lessens the willingness to take risks. It is probable that there is some truth in this point of view for short period changes, but there is no absolute relation between the amount of work the average man is prepared to do and the amount of the real reward that he enjoys. For there have been very wide variations as between different countries in the reward, without any corresponding variation in the amount of effort given, and in a particular country, England, for example, it cannot be said that willingness to work has varied directly with the real reward for effort, which has multiplied fourfold in the last 100 years. Indeed, strong counter tendencies are always in operation and high taxation may often lead to greater effort in order to maintain the net standard of living at the original point. It is probable that sudden changes in taxation do affect the willingness to take risk directly, but "tolerance" sets in rapidly.

Income Tax and Saving.—In regard to the effect upon savings, it is obvious that a large sum taken in taxation diminishes the fund out of which saving takes place. It may be that the whole of the taxation is drawn from money that would otherwise be spent, and that savings are kept intact, but there is strong evidence for the view that taxation trenches upon both saving and spending, though in different proportions, according to the psychology of the individual. It has to be remembered that there is no single simple motive for all saving of all kinds and that a high net rate of interest for certain classes of saving can diminish the effort that is being made, inasmuch as a given total sum can be more easily reached. On balance, however, when consideration is given both to scope and to incentive, high taxation diminishes savings.

Whether high income taxation is worse in this respect than other forms of taxation for an equivalent amount is a nice point dependent upon the industrial habits and the psychological character of the people. So far we have considered the effect upon individuals acting on their personal volition, but a large part of modern industry is conducted by corporate bodies actuated by rather different motives. In this instance, income tax which is levied upon the whole profits is said to diminish the amount put to reserve, and, therefore, the funds available for further exten-

sions. Probably this is the case, but there is no corresponding effect on incentive, for income tax, whether high or low, is passed on as a deduction from dividends, and the conscious effort of profit-making by the management is not usually touched by its amount. Income tax in a particular country has important economic influences upon other countries, inasmuch as the income of its people is never entirely self-contained; it draws income from beyond its borders to its nationals living within them, and it makes income within its borders which goes to people living beyond them. Two separate income tax systems in two countries having economic relations of this kind have most important reactions of an economic character. The problem of double taxation is so far only partly solved. It acts as a kind of artificial barrier in the international flow of capital, inasmuch as funds are prevented from flowing from the point where they are most abundant to the point where they are most needed. Contrary to popular impression, the real burden of double taxation is on the borrowing country, and not upon the lender, although the latter often appears to suffer it.

In elaborating methods of income taxation, the pursuit of ideals connected with justice as between individuals with widely different incomes may have to be reconciled with disadvantages of a social or industrial character. Thus, highly progressive rates may be "fair," but they may also be socially inexpedient, especially where they trench upon the fund for savings, and the population with smaller incomes, who reap the benefits of the progression, are not prepared to make good the deficiency, or are unaware of its existence. A fall in the national fund of savings must ensue, with economic reactions upon total productivity.

INCOME TAX: IN PRACTICE. War provides a fertile soil for the roots of taxation. Perhaps the earliest income tax in England is to be found in the old land tax. After the Revolution the war with France led to a considerable sum of revenue being raised on the land. The land tax imposed in 1692 continued to draw supplies from this source, but in addition it imposed a tax of "4 sh. in the £ according to the true yearly value" of any "estate in goods, wares, merchandise, or other chattels, or personal estate whatsoever within this realm." In addition, it imposed a similar tax upon the profits and salaries of all persons having any office or employment of profit, except naval and military officers. It is not known how the duty on personal estate was levied, or what was its proportion in the quotas of the total land tax raised. All that is known is that over the course of years the yield of the tax on personalty dwindled almost to nothing.

Pitt's Income Tax, 1799.—A century later the financial necessities of the further wars with France, the Napoleonic Wars, led to the return to the income tax as a financial instrument. Ignoring an attempt to link the old assessed taxes on carriages, horses, men-servants, etc., to the amount of the taxpayer's income in the form of duties, which were called the "triple assessment," a regular income tax was imposed in Great Britain in 1799 by William Pitt. The taxpayer was asked to state his income from all sources but incomes under £60 were exempt. The general rate of tax was 10%, which was applied to all incomes of £200 and upwards. For incomes between £60 and £200 the rate was graduated, while certain deductions were allowed for children and repairs to property. Some of these refinements of taxation proved, however, to be before their time. Abused by the taxpayer they were erased from the statute book and revived only in modern times. After the Treaty of Amiens in May 1802 this early statute was repealed.

When war was resumed in 1803 a new income tax act was enacted, framed on lines which were so soundly based as to remain, in essence, the framework of the modern law. Not only were the sources of income divided into the five great classes which

remain with us to-day as schedules A, B, C, D and E, but the principle of collection of the tax at the source was introduced. The former statements of total income were abandoned; in their place were required statements of income from particular sources. So potent was the new principle of collection at the source that the yield of the tax, notwithstanding the reduction of the rate from the 10% of 1799 to a rate of 5%, was almost equal to that under the earlier act. During the century and a quarter that has since elapsed, this principle has continued to be the mainstay of the productivity of the tax.

Peel's Income Tax, 1842.—After Waterloo the tax was repealed, but it was revived again by Sir Robert Peel in 1842 as part of his scheme of the reorganization of the national finances. Peel's act of 1842 levied the duties under the five familiar schedules, and the tax in its general structure, principles and scheme of administration closely resembled Pitt's act of 1803 as modified by an act of 1806, in which the deductions for children and the allowances in respect of repairs to property were withdrawn.

Apart from the exclusion of Ireland from the scope of the tax, an omission which was rectified in 1857, the tax as set out in Peel's act was not seriously modified until quite modern times. In 1842 the exemption limit was raised to £150, but when in 1853 the tax was made effective throughout the United Kingdom it was reduced to £100. In 1876 the old limit of £150 was restored and increased in 1894 to £160, at which figure it remained until the outbreak of the World War led to its reduction in 1915 to £130. The rate of tax has varied greatly. At the date of its repeal in 1815 it was 2s. in the pound. In the second half of the 19th century its general level may be said to have been from 6d. to 8d., although it was as low as 2d. in 1874 and 1875. The South African War brought the rate beyond the one shilling mark, while the World War pushed it up to a maximum of six shillings. Ten years of peace have brought it back to four shillings.

Graduation.—Graduation in some degree or other has almost always been a characteristic of the tax. During its earlier years it was of little effect, inasmuch as its application was restricted to the lower incomes, more or less as a practical necessity. A proposal to extend it to the higher incomes evoked from Lord Brougham the opinion that such a system would be a gross and revolting absurdity. Harcourt in 1894 effected a slight extension of the graduation but he could not be induced to proceed beyond incomes of £500. A similar attitude was adopted throughout the 19th century towards the principle of differentiation, that is, the principle of charging earned income at a lower rate than that applied to investment income. Select committees in 1851 and 1861 were hopelessly divided in their views upon this method of relief. It was left to Asquith to appoint the select committee of 1906 to consider the practicability of both graduation and differentiation. Upon the recommendations of this committee both principles found a final acceptance.

Graduation and Differentiation, 1907.—The Finance Act of 1907 gave earned income in the enjoyment of a taxpayer whose total income did not exceed £2,000 immediate relief of one-quarter of the normal rate of one shilling. Later acts have so refined upon the principle that it is now firmly embedded in the British income tax system. The principle of graduation came into its own in the same act of 1907 through the introduction of a super-tax upon incomes over £5,000, which was imposed as an additional tax of 6d. in the £ on the amount by which the income exceeded £3,000. Here also later acts have changed the weight and range of the graduation but have left the principle inviolate.

In 1918 all the numerous income tax enactments were consolidated into one statute in the Income Tax Act, 1918, which came into force on April 6, 1919. A comprehensive examination of the whole income tax system was conducted by the Royal Commission on the Income Tax in 1920. Following its recommendations changes were made in the method of granting the differentiation relief and in applying the principle of graduation. The relief introduced in 1916 in respect of double taxation, so far as it arose from dominion income taxes, was put upon a permanent footing. The commission also made recommendations in a number of minor matters, some of which have been duly incorporated

into the law and others of which, including a resolute attempt to deal with the evils of evasion, still remain to be fully implemented.

THE UNITED KINGDOM

The British tax has been developed gradually in detail, reflecting at various stages in its history the growth of opinion, equality and justice, until to-day it is a financial instrument of great intricacy, subtlety and power. None the less the broad scheme of the law has remained unchanged in many essential characteristics for nearly a century. Flexibility is provided by the annual re-enactment of the whole income tax code through the medium of the continuation clauses in the yearly Finance Act, which serves also as the medium for amendments, extensions and declarations of the construction of the law.

The salient characteristics of the tax may be grouped under nine heads.

Scope.—The tax extends, broadly speaking, to all income arising in the United Kingdom by whomsoever it may be enjoyed, and to all income accruing to persons residing in the United Kingdom without regard to the place where it may arise. The tax walks, so to speak, upon the two legs of origin and residence. It therefore leads to the problems of double taxation. Provisions for relief against this defect, resting upon the principle of division of the total tax between the two taxing jurisdictions, exist as respects income liable both to United Kingdom tax and tax in any of the British dominions overseas, except in the case of the Irish Free State, where the relief is based upon the principle of charging tax only in the country of residence. Further provisions for double taxation relief also exist as respects profits on shipping. One code of laws applies, generally speaking, to individuals, partnerships, companies and other bodies of persons. In the main the tax is a tax on the incomes of individuals, nearly 90% of the total actual income brought into charge being distributed among individuals who are actually resident in the United Kingdom.

Administratively, the tax is levied under five separate categories or schedules of income. But this is a matter of machinery only, and the tax borne by individuals is in reality only one tax on the total income of the individual, and not, as is often thought, a series of taxes on the separate sources of his income.

Definition of Income.—In respect of the ownership of lands, houses, etc., in the United Kingdom (schedule A) the measure of income is the annual value, which means broadly the rent at which the property is let, or is worth to be let by the year (the tenant bearing his usual rates and taxes), less certain statutory deductions for repairs. Relief may also be obtained on an average cost of additional expenditure on repairs, maintenance, insurance and management. Annual value is determined periodically.

In respect of the profits on occupation of land in the United Kingdom (schedule B), the measure of profit is made on a conventional basis, which assumes profits bearing, in the case of land used mainly for the purposes of husbandry, a fixed relation of equality to the annual value of the land occupied. In other cases it is a relation of one-third of the annual value.

No definition is necessary in the case of interest on public funds (schedule C). Income (schedule D) from dominion and foreign securities (other than public debts) or from foreign and dominion stocks, shares and rents is normally liable on the full amount of the income, less charges which must necessarily be met abroad.

There remain the two main classes: income from trades or professions (schedule D) and income from employments (schedule E). Here the broad rule is that the income to be charged is the excess of the gross receipts over the expenses incurred wholly, necessarily and exclusively in earning the profits or income in question.

The British income tax, in the words of one of the judges, "is a tax on income," and this is strictly construed by the exclusion from the scope of the tax of profits which are in the nature of capital gains; in this respect the British system is strikingly different from that in force in the United States of America. In consequence, the law prohibits, in arriving at profits for income tax purposes, any deductions in respect of capital charges, lost

income or losses unconnected with the business. Provision is, however, made for a deduction from the statutory profits liable to tax of an allowance in respect of the depreciation of machinery or plant.

Computation of the Statutory Income.—Subject to certain exceptions, the statutory income liable to be taxed for any year of assessment (a year running from April 6 to the following April 5) is—in the case of the variable incomes derived from trades, manufactures, professions and employments (except those of wage earners), and also in the case of income from investments (other than property in the United Kingdom) received without deduction of tax—the actual income of the preceding year. In the case of business profits, the trading year usually replaces the fiscal year. Income from property (schedule A), from the occupation of lands (schedule B), from interest on public funds (schedule C), from wages, and all income taxed by deduction under the principle of collection at the source (*vide* Collection of the Tax) is computed, when ascertaining the statutory income of the year of assessment, at the amount of the income assessed for, or earned, or taxed by deduction (as the case may be) in that year.

Computation of the Tax.—For the year 1928-29 income tax is charged at a standard rate, and, in the case of an individual whose income exceeds £2,000, at a rate or rates exceeding the standard rate in respect of fixed sections of income above that amount. For 1927-28, the scale of these rates, known up to 1927-28 as rates of super-tax, but after that year as rates of sur-tax, is set out under rates and yield of tax.

Differentiation.—This is the principle of granting a relief from the full weight of the tax on earned income. Introduced in 1907, by means of a reduction of the normal rate of income tax, and changed in 1920 to the method of deducting from the earned income of an allowance of part of that income, subject to a maximum, the method in force from 1928-29 is as follows. From the tax computed at the standard rate is deducted an allowance of tax, at that rate, on one-sixth of the amount of the earned income, subject to a maximum deduction of the tax on £250.

Graduation.—This is the principle of charging a heavier rate of tax upon large incomes than upon small. From the inception of the tax, graduation in some form or other has been among its characteristics. From 1920-21 to 1927-28 inclusive, after deducting from the total of the statutory income from various sources the allowance in respect of earned income (*vide* Differentiation), there was deducted from the balance, called the assessable income, an aggregate of various personal allowances and deductions (*e.g.*, for self or self and wife, children, house-keeper, dependant relatives, etc.), leaving a balance called the taxable income. The first £225 of this taxable income was charged at half the standard rate, and the balance, if any, at the full standard rate. From 1928, the reliefs are granted in terms of tax, instead of in terms of income. In other words, from the total tax calculated at the standard rate on the aggregate statutory income is deducted tax, calculated at the standard rate, on the personal allowances and deductions. Further deductions of tax are made of (a) half the tax remaining chargeable, or half the tax at the standard rate on £225, whichever is the less, and (b) tax at certain defined rates on the amount of life insurance premiums, within fixed limits, and on the amount of income which has already borne dominion income tax.

If the system of graduation stopped at this point, the relevant curve would rise steeply until incomes in the neighbourhood of £2,000 were reached, but after that point it would flatten rapidly. To continue the graduation, rates of sur-tax (before 1928-29 the name was super-tax) are charged on sections of income above £2,000 in the case of individuals. Sur-tax is expressed to be a deferred instalment of income tax. It is normally payable on or before Jan. 1 following the end of the year of assessment for which it is payable. For administrative reasons, sur-tax is assessed and collected, under the aegis of the special commissioners of income tax, separately from the income tax. The effect of this system as a whole is to levy an effective rate of tax on each £ of the total statutory income of an individual, rising gradually from a fraction of a penny in the £ until the rate closely approaches a

maximum rate represented by the sum of the standard rate of income tax and the highest rate of sur-tax.

The following table of the amount of income tax and super-tax and the effective rate of tax per £ of income on specimen incomes clearly illustrates the graduation of the tax in the case of married couples without children for the year 1927-28. It shows how the effective rate rises in the case of earned income from 2d. in the £ for a total income of £300 by gradual stages up to 9s. 7½d. in the £ on an earned income of £150,000. The rate for investment income rises from 2½d. for an income of £250 to 9s. 7½d. for one of £150,000. Plotted on a graph, these effective rates fall upon a very smooth line unbroken by any abrupt jumps.

GREAT BRITAIN: *Income Tax and Super-tax. Married Couples Without Children, 1927-28*

Total income	If income all "earned" income		If income all "investment" income

Collection at the Source.—Perhaps the most famous characteristic of the British tax is the principle of collection at the source. Under this principle the tax is obtained, whenever it is possible to do so, by deducting it before the income reaches the person to whom it belongs. The formal assessment is accordingly laid, wherever this course is possible, on each source of income by itself and on persons who are debtors in respect of income belonging to other persons. Power is given to the payer of income to deduct the appropriate tax from the payments made to the ultimate proprietors of that income. For instance, a limited liability company is assessed to tax at the standard rate on the whole of its profits, without reference to their ultimate destination. On paying interest to its debenture holders, or dividends to its shareholders, the company is entitled to deduct and retain tax at the standard rate on the interest paid or dividends distributed, and the investor thus receives his interest or dividend subject to this deduction of tax. It is estimated that approximately two-thirds of the net yield of the tax is collected at the source.

With the exception of tax collected at the source on interest on public debts, and on income from foreign dividends, etc., which is paid at or shortly after the time of payment of the income from which the tax is deducted, income tax contained in the main assessments for the year is due and payable on or before

Jan. 1 in the year of assessment; tax contained in additional assessments signed after that date is payable on the day after the date of signature. To this general rule there are, however, some other important exceptions. The tax charged on any individual or firm in respect of lands occupied for husbandry, or in respect of a trade, profession or vocation, and of most employments, is payable in two equal instalments, the first on or before Jan. 1 in the year of assessment and the second on or before the following July 1. Manual wage earners assessed half-yearly pay tax in respect of each half-year. Tax in respect of employments under the Crown is deducted (usually quarterly) at the source.

Administration.—The responsibility for assessment and collection of a very large part of the tax is laid upon local bodies of commissioners possessing certain property or other qualifications, which are appointed for certain cities and boroughs and for parts or all of a geographical county. The commissioners are independent of official control; they appoint their clerk, and (except in respect of certain areas or functions) assessors of taxes and collectors of taxes; on them falls the statutory duty of signing and allowing assessments made either by the assessor or the additional commissioners (the name given to those who make assessments on trade profits) and of hearing and determining appeals against such assessments. Fitted into this scheme is the officer of the Crown, known as H.M. inspector of taxes. In law his part is primarily to safeguard the interests of the revenue with strictly defined rights of intervention and objection at various stages of the formal procedure laid down by the statutes.

This broad scheme is honeycombed with exceptions. There are the special commissioners of income tax, each of whom, still independent of the revenue authority, is appointed by the Treasury. Then there are commissioners for the various public departments of State. The Bank of England and the National Debt Commissioners also act as commissioners. Again, all assessments on manual weekly wage earners which are for a half year only are made by H.M. inspector of taxes. The taxpayer normally charged by the district commissioners may, if he wishes, elect to be dealt with by the special commissioners, and even if he allows his assessment to be made by the district commissioners he may take an appeal against that assessment to the special commissioners.

During the past 50 years income tax has grown so much in importance and complexity that its efficient administration has compelled a considerable development of the methods of administration. In practice, the inspector of taxes carries out, with the full concurrence of the various bodies of commissioners, most of the duties that are vitally essential to the smooth-working efficiency of the machinery of administration. Nevertheless, the key functions of the district commissioners have been preserved throughout. In the absence of any detailed accounts or other evidence, it is the additional commissioners who determine the amount of the assessment upon business profits; even more important, the general commissioners retain their appellate functions and so stand in an independent and impartial position between the taxpayer and the representative of the revenue.

Rates and Yield of Tax.—In 1920-21 a new system of differentiation and graduation was introduced in accordance with the recommendations of the Royal Commission on the Income Tax of 1920. In 1927-28 the effective exemption limit was £135 of assessable income, or £162 in terms of earned income. For married persons these figures change to £225 and £270. The total number of individuals within the scope of the tax in 1925-26 was estimated at 4,600,000.

The standard rate of tax for the three years 1925-26 to 1927-28 was four shillings in the pound. For 1925-26 the total statutory income of persons liable to the tax for the new United Kingdom of Great Britain and Northern Ireland was estimated at £2,375,000,000. In 1926-27 the Exchequer receipt was £234,717,000 and it was estimated that the collection in 1927-28 would amount to £247,000,000.

The preceding figures relate to income tax alone and do not include the yield of the super-tax. The point at which liability to this tax commences is £2,000. The scale of rates of tax in force since 1925-26 is given below. In 1925-26 the number of indi-

viduals to be charged was estimated at 97,000, with a total income of £558,000,000. The estimated net super-tax payable for that year was £58,000,000.

Scale of Rates of Super-tax

	Rate in the £ s d	
On the first £2,000 of the income	nil	
On the next £500 (to £2,500)	9	0
On the next £500 (to £3,000)	1	0
On the next £1,000 (to £4,000)	1	6
On the next £1,000 (to £5,000)	2	3
On the next £1,000 (to £6,000)	3	0
On the next £1,000 (to £7,000)	3	6
On the next £1,000 (to £8,000)	3	6
On the next £2,000 (to £10,000)	4	0
On the next £5,000 (to £15,000)	4	6
On the next £5,000 (to £20,000)	5	0
On the next £10,000 (to £30,000)	5	6
On the remainder (above £30,000)	6	0

BRITISH DOMINIONS

Taxation according to faculty, that is, direct taxation, based upon the principle of ability to pay, so early established in Great Britain, was naturally carried overseas to the various British possessions. It is not therefore surprising to find income taxes firmly established to-day in South Africa, in the provinces and protectorates there as well as in the Union, in Canada, where also there are provincial income taxes as well as the Dominion tax, Australia, where a similar widespread use of the tax is made, New Zealand, India and in most of the West Indies. Naturally also there is a strong family resemblance between the various income tax systems, most of them having been strongly influenced by British law. Income is usually defined broadly but comprehensively, but there is a general absence of the schedular arrangement of the British tax. Broadly speaking, the year preceding the year of assessment is favoured as the basis of computation of the income to be charged. The minimum amount of income exempted from tax varies, but personal allowances to the taxpayer, his wife and children are general. Graduation of the tax is a common feature, and the device of an additional tax, or super-tax, is freely adopted. In some dominions, graduation is extended also to companies. The methods of graduation range from simplicity to formulae of great complexity. Differentiation in favour of earned income is found, but is not widely favoured. Taxation at the source is a frequent feature, especially in respect of dividends paid by companies. The rates of tax vary widely, as may be expected from the range of budget requirements of communities of different populations and varying degrees of wealth. As a rule, the income tax in the British dominions overseas is one tax levied upon the base of the total income, irrespective of the nature of the components of that income. In this respect, the British tradition is followed.

INCOME TAXES IN EUROPE

Income taxes of various kinds have been adopted by all the European States except Switzerland (where, however, several cantons levy such taxes). The following is a brief outline for 1928 of those imposed by France, Germany and Italy.

France.—France levies seven subsidiary income taxes (on individuals and companies, generally on income arising in France) and a general income tax (on the aggregate income of individual residents). The income year is, in general, the preceding calendar (or business) year.

(1) *Industrial and Commercial Profits Tax* (*Impôt sur les bénéfices industriels et commerciaux*) (excluding mining profits, see [7]), with special treatment for insurance and financial under-

takings. Rates—for profits up to 50,000 fr. lump sums are payable, ranging from 22.50 fr. (profit under 800 fr.) to 6,750 fr. (profit between 45,000 fr. and 50,000 fr.); for profits exceeding 50,000 fr., 15%; insurance and financial undertakings, 20%.

(2) *Agricultural Profits Tax* (*Impôt sur les bénéfices de l'exploitation agricole*), on rental value, increased by 75% and multiplied by 3 (or 2.5 for wheat-lands, or 5 for market-gardens, etc., and woodlands worked commercially), or on the preceding year's profit, if less. Exemption limit, and abatement, 2,500 fr., with partial abatements for the income between 2,500 fr. and 8,000 fr. Rate, 12%.

(3) *Salaries, etc., Pensions and Annuities Tax* (*Impôt sur les traitements, etc., salaires, pensions et rentes viagères*). Exemption limit, and abatement, 7,000 fr., with allowances for wife, children and dependants and partial abatements for the income between 7,000 fr. and 40,000 fr. Rate, 12%.

(4) *Non-commercial Professional Profits Tax* (*Impôt sur les bénéfices des professions non-commerciales*). Exemption limit, abatements and rate, in general, as in (3).

(5) *Immovable-property Tax* (*Impôt foncier*), comprising: (a) *Buildings Tax* (*Contribution foncière des propriétés bâties*), on rental value, less allowance for maintenance and depreciation—rate, 18%; (b) *Land Tax* (*Contribution foncière des propriétés non bâties*), on rental value (less allowance for upkeep and exhaustion) increased by 75%—rate, 18%.

(6) *Dividend and Interest, etc., Tax* (*Impôt sur les revenus des valeurs et capitaux mobiliers*), comprising: (a) *Taxe sur le revenu des valeurs mobilières, sur les primes de remboursement et les lots*, on dividends, debenture interest, premiums, etc., payable by French companies and municipalities—rate, 18%; (b) *Taxe sur les valeurs étrangères*, on income from foreign shares, etc., and from foreign Government securities—rate (if the shares, etc., are introduced into France by the issuing companies, etc.), 18% (if the securities are of foreign Governments, or are introduced into France by individuals and not by the companies, etc., concerned), 25%; and (c) *Taxe sur le revenu des créances, dépôts et cautionnements*, in general on deposit and mortgage interest—rate, 18%.

(7) *Mine Levy* (*Redevance proportionnelle des mines*), in general on all mines (except salt mines) in France, in respect of (a) their area and (b) proceeds from the winning and exploitation of coal and minerals. Assessment in (b), for a joint-stock company, is based on the dividends distributed; for other cases, on the net profit. Rates, 1.8 fr. per hectare (about 2½ ac.) and 25% on the dividends or profit assessed.

(8) *General (or Supplementary) Income Tax* (*Impôt général sur le revenu*), including, besides income chargeable under (1) to (7), that from French Government securities and from abroad. (Foreigners with habitual residence in France are assessed upon seven times its rental value, unless their income from French property, business or profession exceeds that amount.) Exemption limit, and abatement, 7,000 fr., with allowances for wife, children and dependants. Rates range, in a scale of 25 "steps," from 1.20% on the portion of income between 7,000 fr. and 20,000 fr. to 30% on the portion above 550,000 francs. (Tax so computed is increased by 25% if the taxpayer is over 30 years old and unmarried or divorced, without a child or dependant; or by 10% if over 30 years old and at least two years married, without a child or dependant.)

In (1) to (5) and (8), in addition to the income allowances for children and dependants already mentioned, further allowances under those heads are made as deductions from the tax computed.

Poujol, *De la superposition d'impôts cédulaires en matière de revenu des capitaux mobiliers en France* (1927); E. Besson, *Traité pratique des impôts cédulaires et de l'impôt général sur le revenu* (4th ed., 1927), with 1928 supplement.

Germany.—Since 1920 the taxation of income has been reserved to the Reich, which levies:

(1) *Income Tax* (*Einkommensteuer*) (on individuals, includ-

ing members of ordinary partnerships), assessed on the aggregate income of residents in Germany and on the German income of non-residents. The income year is, in general, the preceding calendar (or business) year. Changes during the income year in the value of business buildings and movable property are taken into account in computing income. Wages are taxed through deduction by the employer. Exemption limit, in general, R.M. 1,300, with additions for wife and children; abatement, R.M. 720 (restricted to incomes up to R.M. 10,000), with allowances for wife and children. Rates—incomes up to R.M. 8,000, and all wages, 10%, less 15% reduction (not to exceed R.M. 24); incomes over R.M. 8,000, from 10% on the first R.M. 8,000 to 40% on excess over R.M. 80,000; non-residents' income, if not from agriculture, business or profession, 10%. (If total income does not exceed R.M. 20,000, a partial set-off of income tax is made for dividends, etc., from companies liable to corporation tax.)

(2) *Corporation Tax* (*Körperschaftsteuer*) (on joint-stock concerns), in general with the same scope, income year and treatment of changes during the income year in the value of business buildings and movable property, as the income tax. Rates—in general, 20%; for certain banks, co-operative societies, etc., 10%; for private limited companies and co-operative societies, with capital or assets not exceeding R.M. 50,000, from 10% on the first R.M. 8,000 income to 30% on excess over R.M. 28,000 (but the maximum rate on their total income is 20%).

Ball, *Einführung in das Steuerrecht* (4th ed., 1927, bibl.); Dr. Rehdans and Dr. Selle, *Die Besteuerung der Ausländer im Deutschen Reich* (1927); Dr. Pissel and Dr. Koppe, *Das Einkommensteuergesetz* (2nd ed., 1928).

Italy.—Italy levies three subsidiary income taxes (on individuals and companies) and a general income tax (on individuals), with a bachelors' tax (partly an income tax).

(1) *Land Tax* (*Imposta sui terreni, Imposta fondiaria*), distinct from the agricultural profits tax (see [3], Class B) and assessed on rental value. Rate, 7½%.

(2) *Buildings Tax* (*Imposta sui fabbricati*), on rental value (less allowance for repairs, etc.), except of buildings used industrially, the income from these being dealt with in (3), Class B. Rate, 7½%.

(3) *Movable Property Income Tax* (*Imposta sui redditi di ricchezza mobile*), on income not charged to (1) or (2), arising in Italy or accruing abroad to an Italian resident (foreign dividends and interest, and interest on certain loans contracted abroad since 1922 by Italian companies and public authorities, being exempt). The income year is, in general, the preceding year to June 30 or preceding business year. Investment incomes and salaries, etc., are taxed by deduction. The tax comprises five classes:

Class A, investment income—rate, 20%. Class B, business, mining and agricultural income—exemption limit (total income from all sources): (1928) 1,000 l.; (1929 et seq.) 2,000 l.—abatement; (1928) 400 l. (incomes up to 3,000 l.); (1929 et seq.) from 1,000 l. (incomes between 2,000 l. and 2,100 l.) to 200 l. (incomes between 2,400 l. and 2,500 l.)—rate (1928) 16%; (1929 et seq.) 14% (agricultural income is charged half these rates). Class C, income from professions or arts—exemption limit and abatement, as in B—rate (1928) 14%; (1929 et seq.) 12%. Class C2, salaries, pensions, annuities, etc. (other than as included in D)—exemption limit, as in B—abatement; (1928) 240 l. (incomes between 1,000 l. and 1,120 l.) or 160 l. (incomes between 1,120 l. and 1,280 l.); (1929 et seq.) as in B—rate, 9%. Class D, salaries, pensions, etc., from the State and certain public bodies—exemption limit, as in B—abatement; (1928) 100 l. (incomes up to 2,000 l.); (1929 et seq.) as in B—rate (1928) 9%; (1929 et seq.) 8%—in the case of wages of workmen employed by the State and certain public bodies the rate is 4%.

(4) *General (or Supplementary) Income Tax* (*Imposta complementare globale progressiva sul reddito*), on residents (including foreigners living in Italy for at least one year), for all Italian income and the portion of their foreign income enjoyed (*goduto*)

in Italy—and on all residents abroad, for all Italian income. The income year is in general as in (3). Five per cent (limited to 3,000 l.) is deducted for each child or dependant (excluding wife). Exemption limit, 6,000 l. (before allowing for children, etc.) or 3,000 l. (after allowing for them). Rates generally range, in a much subdivided scale, from 1% on incomes between 3,000 l. and 3,025 l. to 10% on incomes exceeding 995,000 l.

(5) *Bachelors' Tax* (*Imposta personale progressiva sui celibi*), on bachelors (except, *inter alia*, foreigners and Catholic clergymen) between 25 and 65 years old, is in general a lump sum (35 l., 50 l., or 25 l., where the ages are between 25 and 35, 35 and 50, 50 and

65 respectively) plus one-fourth of the general income tax (see [4]) due by the taxpayer.

†Without deduction for deficits shown on returns of corporations reporting no net income.

**For net incomes of \$5,000 and over, this exemption was reduced to \$2,000.

century, no successful use of the general income tax was made in the United States until the Civil War; and the income taxes then adopted were soon thereafter repealed, or fell into practical disuse. The demand for effective income taxation, however, showed great vitality. It kept moribund income tax laws on the statute books in several States; led to abortive experiments with the tax, particularly in the '40s and '90s; and finally in 1909 resulted in the adoption of a Federal excise tax "with respect to the carrying on or doing business" by corporations, equivalent to 1% of the annual net income over and above \$5,000. This proved to be in substance an effective income tax.

State Income Taxes.—In 1911 the State of Wisconsin adopted a general income tax law applicable to individuals, partnerships and corporations. The practical success of this tax encouraged other States to adopt similar laws or to vitalize the administration of unsuccessful income tax laws already on the statute books; and although a few States either repealed or rejected the tax, in 1927 14 States had income taxes. Of these States, nine taxed the income of both individuals and corporations; three taxed the income of corporations only; and three taxed only personal incomes. The adoption of income taxes by the States has been largely for the purpose of replacing the unsatisfactory personal-property tax (particularly on intangible personal property) and the so-called corporation franchise tax. The newer State income taxes are generally administered by State or central authority, but provide for the return of a substantial portion of the tax to the county or local governments. There is an increasing tendency to assess the tax on the basis of the Federal income tax return and an effort is made by apportionment devices to exempt in whole or in part business or corporation income derived from property located and business transacted outside the State. Jurisdictional questions and multiple taxation thus constitute fundamental problems. The various State income taxes differ considerably in their exemptions and rates, but in general the rates are much lower than in the Federal tax, the highest rates—in North Dakota—ranging from 1% to 6% on incomes in excess of \$10,000. However, the combined Federal and State taxes represent a serious burden on the larger incomes.

Federal Income Tax.—The foundation for the Federal system of income taxation was laid by the ratification, on Feb. 25, 1913, of the 16th amendment to the Constitution, which provides:—

That Congress shall have power to lay and collect taxes on incomes, from whatever source derived without apportionment among the several States, and without regard to any census or enumeration.

The development of the Federal income tax is suggested in the accompanying tabular statement. Under the Revenue Act of 1928 the income tax carries exemptions of \$1,500 for single individuals, \$3,500 for heads of families and \$3,000 for corporations with net income below \$25,000. Under the personal income tax there is a further specific exemption of \$400 for each child under 18 years and for every dependent incapable of self-support. Individuals are subject to a split normal tax of 1½% on the first \$4,000 of taxable income, 3% on the next \$4,000 and 5% on the remainder; and to a surtax ranging from 1% of the net income between \$10,000 and \$14,000, to 20% on the net income in excess of \$100,000. Corporations are subject to a flat rate of 12%. Earned income (to the extent of \$30,000) is taxed 25% less than unearned income, all incomes of \$5,000 or less being considered as earned. Net income is defined as all income and gains "from whatever source derived," excluding certain specific classes of income and less certain specific deductions.

The most important characteristic of the Federal income tax is its striking productivity, the elasticity of which is illustrated in the table. The present exemptions are high compared with similar exemptions allowed in other countries, and only a small proportion of the population is directly affected by the tax. A large proportion of the tax is collected in the industrial or urban States and is thus marked by some unfortunate class and sectional characteristics. Compared with similar taxes of other countries, the rates on small and moderate incomes are low, while the rates on the larger incomes were, until the year 1925, unusually high. From the technical standpoint, the striking charac-

teristics of the Federal tax are: The high ratio of surtax to normal tax; the marked difference in the normal tax applicable to individuals and corporations respectively; its failure, largely because of constitutional limitations, to reach interest on municipal bonds and other tax-free securities; the small use of "stoppage-at-source" (whereby the normal tax is withheld and paid direct to the Government by payers out of payments due to corresponding payees); and the credit accorded for income and profits taxes paid to foreign countries on income derived from sources therein. The American tax reveals a gradual approach to the British position on capital gains and losses, which are taken into account at a special rate of 12½%.

The complexity of the tax has, in the past, led to great delay in the settlement of the larger tax cases; and there was, in 1928, a disturbing congestion of appeals pending before the Board of Tax Appeals (a joint administrative and judicial tribunal, created in 1924, whose decision is final unless modified on appeal by the higher Federal courts). A continuing agency, the Joint Committee on Internal Revenue Taxation, was instituted by the Revenue Act of 1926 for the purpose of scrutinizing the application of the tax, checking refunds and devising methods of simplifying the income tax and of improving its administration. The committee concluded that a net income tax, applicable to the complex conditions of modern business, cannot be made "simple"; but, as a result of its investigations and the effective co-operation of the Treasury Department, the work of assessment has been greatly speeded up, final and conclusive settlements are being reached in a larger proportion of cases, the technical and administrative provisions of the law have been made more certain and the entire law re-arranged and clarified in the Revenue Act of 1928. While hundreds of the old "war cases" still remain to be settled by the Board of Tax Appeals or the courts, they are being rapidly cleaned up, and the income tax has now plainly entered the post-World War period of development.

INCONVERTIBLE PAPER CURRENCY, the name given to paper money not exchangeable for gold at the demand of the holder, and therefore possessing no title of intrinsic validity. When a bank-note is exchangeable on demand for gold, as for example is the case with a Bank of England note, it is in effect a gold certificate and is therefore accepted by anyone, anywhere, at its face value. When a Government prints paper money, and refuses to honour it by converting it on demand into metallic money, the inconvertibility of such currency makes it unacceptable as good money, and it falls below face value to a point determined by the quantity issued. For a discussion of the important issues involved see **BANKING AND CREDIT**; **CURRENCY**; **MONEY**; **PAPER MONEY**.

INCORPORATION, in law, the embodying or formation of a legal corporation, brought about either by a general rule contained in such laws, e.g., as the Companies Acts, or by a special act of sovereign power, e.g., an incorporating statute or charter. The word is used also in the sense of uniting; e.g., a will may incorporate by reference other papers, which may be then taken as part of the will, as much as if they were set out at length in it. This term is used similarly in the United States.

INCREASING RETURNS. In economics, a term used to describe a condition of production in which the application of additional capital and labour produces a greater proportionate return. Alfred Marshall, in his *Principles of Economics*, points out that while the part which nature plays in production shows a tendency to diminishing returns, the part which man plays shows a tendency to increasing returns. This leads to the following definition of the law of increasing return: "An increase of capital and labour leads

generally to an improved organization, which increases the efficiency of the work of capital and labour." Therefore, "in those industries which are not engaged in raising raw produce an increase of capital and labour generally gives a return increased more than in proportion." See *ECONOMICS; DIMINISHING RETURNS*.

INCREMENT VALUE DUTY. A duty called by this name was first imposed by the Parliament of the United Kingdom in 1910, the tax being one of the highly controversial measures contained in the Finance Act 1909-10. The rate of duty was one pound for every complete five pounds of the "increment value" of any land accruing (a) on a sale, or on a lease (other than a mining lease, and other than a lease for a term not exceeding 14 years); (b) on a succession on the death of the owner; (c) on a valuation made every 15th year in the case of land held by permanent corporations. Increment value was defined as the amount by which the site value of the land as defined in the Act should exceed the original site value as ascertained under the provisions of the Act as to valuation. The administration of the tax was entrusted to the Commissioners of Inland Revenue, who were directed "as soon as may be after the passing of the Act" to cause a valuation to be made of all land in the United Kingdom, showing (a) the "site value," and (b) the total value, of the land. The "site value" was to be the value of the land exclusive of buildings and other improvements, which were taken into account in estimating the total value. The "original site value" was the value of the land without improvements on April 30, 1909. The duty was not imposed in respect of agricultural land while the land had no higher value than its market value for agricultural purposes; or in respect of houses of a limited annual value when occupied by the owner; or in the case of agricultural land not exceeding 50 acres in area and £75 per acre in value, when cultivated by the owner. One half of the proceeds of the duty was appropriated for the benefit of local authorities in the United Kingdom in such manner as Parliament might determine. The increment value duty did not fulfil the hopes of the promoters of the legislation, and was, together with the other "land values duties," *i.e.*, the reversion duty and the undeveloped land duty, repealed by Section 57 of the Finance Act 1920. (See also *LAND TAXES; UNEARNED INCREMENT.*) (J. S. S.)

INCUBATORS. Boxes or rooms of special construction designed for the maintenance of a constant internal temperature, usually blood heat or room temperature. The commonest uses of such contrivances are in bacteriology, in the poultry industry and for the rearing of prematurely-born infants.

BACTERIOLOGICAL INCUBATORS

An incubator which will remain with 0.5° C of the adjusted temperature gives sufficiently accurate heat regulation for all ordinary bacteriological purposes.

FIG. 1.—D'ARSONVAL INCUBATOR

apparatus (fig. 1) consisted essentially of a cylindrical water-jacketed chamber *c'*. The water-jacket was heated by gas and there was a gas regulator controlled by the expansion of the water in the jacket. The water expanding by heat rose in the tube *T*; this increased head of pressure acted upon a rubber diaphragm *D*

which was forced outwards thus obstructing the gas flow into the regulator. A great disadvantage of the cylindrical incubator was its inconvenient shape; there was also difficulty of access to the contents as compared with the modern types.

D'Arsonval Incubator.—Some of the older incubators were cylindrical in form, that of d'Arsonval being the best known. This

apparatus (fig. 1) consisted essentially of a cylindrical water-jacketed chamber *c'*. The water-jacket was heated by gas and there was a gas regulator controlled by the expansion of the water in the jacket. The water expanding by heat rose in the tube *T*; this increased head of pressure acted upon a rubber diaphragm *D*

which was forced outwards thus obstructing the gas flow into the regulator. A great disadvantage of the cylindrical incubator was its inconvenient shape; there was also difficulty of access to the contents as compared with the modern types.

Hearson Incubators.—The incubators in use in most bacteriological laboratories at the present time are of the types shown in figs. 2 and 3; they may be heated by either an oil lamp or a

FIG. 2.—HEARSON'S BACTERIOLOGICAL INCUBATOR (HEATED BY A PETROLEUM LAMP)

FIG. 3.—HEARSON'S BACTERIOLOGICAL INCUBATOR (HEATED BY A GAS FLAME)

gas burner or by electricity. The machines illustrated are made by Chas. Hearson and Co., Ltd., London.

In the form heated by a lamp, for which, however, gas can be substituted, the incubation chamber is surrounded by a water-tank (fig. 2, A) and the lowest part of this is traversed by an in-going (L) and an out-going flue. The mode of regulation of the temperature is by means of a thermodynamic capsule which operates the movements of a cap (F) over the main flue (V), and it is identical in its chief features with the method employed in the chicken incubator. The capsule (S) is situated in the upper part of the incubation chamber.

In the other form (fig. 3) for which gas is used exclusively, there are no flues traversing the water-tank. This latter is heated from its conical floor by a burner beneath the incubator. The heat regulation is controlled by a thermostat of the same nature as in the form of incubator just described, but instead of operating by lowering or raising a cap over a main flue, so as to direct the heated gases either through the water-tank if the temperature is falling, or through the main flue directly to the exterior if it is rising, it actuates a gas-governor, so that the flame itself is increased or diminished in size according to the needs of the incubator. The gas-governor (fig. 4) is fixed to the roof of the incubator. The horizontal arm (D) is the same that raises the cap (fig. 2, F) over the flue in the other form of incubator, but in this case it simply acts as the bearer of the sliding weight. Beyond its fulcrum (fig. 4, G) it is continued into a detent-like spur (B) which pushes down upon a button attached to a rubber diaphragm, when the thermostat within the incubator is expanded by a rise in

FIG. 4.—GAS GOVERNOR

temperature. The button thus forced down, more or less completely closes the inlet gas aperture, and so reduces or cuts off the gas supply to the flame. There is a by-pass to prevent the flame from going out completely, and the size of this can be adjusted by the screw (S).

In electrically-heated incubators the regulating mechanism is similar to that shown in fig. 2 except that the arm *D* is not connected to a cap *F* but is fixed to the upper member of a pair of electrical contacts as in fig. 5. Electrical heating units either heat a water jacket or are arranged as a series of resistance wires enclosed in a metal case occupying the position of the water jacket.

In bacteriological laboratories there are two standards of temperature, one chiefly for the culture of non-pathogenic organisms and the other for the pathogenic forms. The first standard of

temperature lies between 18° and 20° C, and the second between 35° and 38° C. But in hot countries, and even in temperate regions during the summer, the external temperature is much higher than the former of these two standards, with the result that many cultures, especially the gelatine ones, are spoiled. The difficulty is often partially overcome by running cold water through the incubator.

Hearson, however, has constructed a "cool biological incubator," in which by an ingenious device the expansion or contraction of the thermostatic capsule deflects a horizontal pipe (C) on the roof (fig. 6), through which runs cold water from an ordinary tap, in one of two directions. If it is deflected so as to open into the tube (D), the cold water passes into the tank (F), where it is warmed by a gas flame, and thence it passes into the water-jacket of the incubator. If it is deflected so as to open into the pipe (E), it then runs through the ice tank (B), containing broken ice, before passing through the water-jacket of the incubator. If it pours into neither of these pipes it then simply passes out through the pipe (H) to the waste pipe (N). By this device the temperature of the incubator can be kept constant at any desired point, even though it may be some 30° to 40° C below that of the external air.

Incubator Rooms.—In large laboratories where a considerable incubator accommodation is required incubator rooms are employed. These are small rooms lined by insulating material and fitted with shelves. The simplest and most satisfactory method of heating is by electricity. A series of electrical heating units are distributed about the room and may be conveniently controlled by a thermostatic capsule. The current consumption is too great for a direct platinum contact as in the electrically-heated incubators; the capsule therefore is made to control a circuit of comparatively low current consumption which in turn operates an electrically controlled switch.

INFANT INCUBATORS

Tarnier's Incubator.—The first incubator designed for rearing children who are too weak to survive under normal conditions, or who are prematurely born, was that of Dr. Tarnier. It was constructed in 1880 and was first used at the Paris Maternity Hospital. Its form is that of a rectangular box measuring $65 \times 30 \times 50$ centimetres (fig. 7). It is divided into an upper and lower chamber; the former contains the infant, while the latter serves as a heating chamber, and in reality is simply a modified water-tank. The partition (P) which divides the incubator into two chambers does not extend the whole length of it, so that the upper and lower chambers are in communication with each other at one end of the apparatus. It is through this passage that the heated air from the lower chamber passes into the upper one containing the infant. The narrow bottom chamber (C) serves to prevent loss of heat from the base of the water-bottles. The outside air is admitted into the lower chamber at the opposite end, through an aperture (A), and passing over a series of bottles (B) containing warm water, becomes heated. The air is rendered adequately moist by means of a wetted sponge (S) which is placed at the entrance of

BY COURTESY OF HEARSON & CO.
FIG. 5.—DIAGRAM ILLUSTRATING CONTACTS AND REGULATOR OF ELECTRIC INCUBATORS

FIG. 6.—HEARSON'S COOL BIOLOGICAL INCUBATOR

FIG. 7.—TARNIER'S INFANT INCUBATOR

the lower chamber into the upper. The warmed and moistened air is determined in its direction by the position of the outlet aperture (O), which is situated above and just behind the head of the infant. It contains a helix valve (H) and the rotation of this is an indication that the air is circulating within the incubator.

The child is kept under observation by means of a sliding glass door (G) situated in the upper or roof wall of the incubator. Immediately beneath this, and attached to one of the side walls, is a thermometer (T) which records the temperature of the air in the infant-chamber. The temperature should be maintained at 31° to 32° C. The precise limit of temperature must of course be determined by the condition of the child; the smaller and weaker it is, the higher the temperature must be.

The warm water vessels contain three-quarters of a pint of water and four of them are sufficient to maintain the required temperature, provided that the external air does not fall below 16° C. The vessels are withdrawn and replaced through an entrance to the lower chamber, which can be opened or closed by a sliding door (D). The walls of the incubator, with the exception of the glass sliding door, are made of wood 25 millimetres thick. Child incubators heated by hot water bottles on the same lines as Tarnier's are still used but need constant attention and have been superseded by machines of the type to be described.

Hearson's Thermostatic Nurse.—This consists fundamentally of an application of the arrangements for heating and moistening the air and for regulating the temperature of Hearson's chick incubator to Dr. Tarnier's human incubator. As in this latter form, there are two chambers (fig. 8), an upper (A) and a lower (B), connected with each other in the same way as in Tarnier's apparatus. The upper chamber contains the infant, but the lower is not a heating but a moistening chamber. Through apertures (M) in the bottom of the lower chamber, the external air passes through, and as in the chick incubator it then passes through perforations in the inner cylinder of a water tray (O) and thence over the surface of the water in the tray, through a sheet of wet canvas, to the chamber itself. Hence it passes to the infant chamber and ultimately leaves this through a series of perforations round the top. The air in both chambers is heated by a warm-water tank. This tank forms the partition which divides the incubator into upper and lower chambers and is made of metal. Through the water contained in it, an incoming (R) and an outgoing (R) to the left) flue, continuous with each other, pass. These two flues are related to each other as in the chick incubator (see POULTRY AND POULTRY FARMING), the inlet flue similarly heating and the outlet flue similarly discharging. The heat-regulating apparatus is identical with that in the chick incubator, and the thermostatic capsule (S) is placed in the upper chamber, near the head of the infant.

The child is placed in a basket which has perforated walls, and is open above. The basket rests upon two shallow supports (D) situated on the upper surface of the water-tank partition. The child is kept under observation through a glass door in the upper or roof-wall of the incubator.

A similar but somewhat improved type of apparatus electrically heated is now manufactured by Messrs. Hearson & Co.

THERMO-REGULATORS OR THERMOSTATS

Certain special forms of thermo-regulators, adapted to the requirements of the particular incubators to which they are attached, have already been described. It remains now to describe other forms which are of more general application. Only those kinds will be described which are applicable to incubators. The special forms used for investigations in physical-chemistry are not described. There are various types of thermo-regulators, all of which fall into one of two classes. Either they act through the

FIG. 8.—HEARSON'S "THERMOSTATIC NURSE"

expansion of a solid, or through that of a liquid. They are adjusted so that at a certain temperature the expansion of the material chosen either cuts down the gas supply or operates a switch which cuts off the whole or part of the electricity supply to the heating units.

Reichert's Thermo-regulator.—This (fig. 9) is one of the simpler forms of gas regulator in which a column of mercury raised by expansion obstructs the gas flow. The stem (S) of the regulator is enlarged above and receives a hollow T-piece (P), the vertical limb of which fits accurately into the enlarged end of the stem, and one end of the cross-limb receives the inlet gas pipe; the other end is closed. The vertical limb of the T-piece is narrowed down at its lower extremity and opens by a small aperture. Above this terminal aperture is a lateral one of the smallest size. From the enlarged end of the stem there passes out a lateral arm (A) which is connected with the outlet pipe to the burner, and lower down another arm (L), which is closed at its outer extremity by a screw (R), is also attached. The stem and lower arm are filled with mercury and the bulb of the stem is placed in the incubator chamber, and gas allowed to pass. When the desired temperature is reached, the mercury in the stem is forced upwards until it closes the aperture of the T-piece, by screwing in the screw (R) of the lower lateral arm (L).

There are several modifications of Reichert's original form. In one of these the screw arrangement in the lower arm is replaced by a piston rod working in a narrow bore of a vertically bent limb of the arm. In another form, the other end of the cross bar of the T-piece is open and leads through a stopcock to a third arm, which opens into the enlarged upper end of the stem opposite to the outlet arm (A); this modification acts as an adjustable by-pass and replaces the minute aperture in the side of the vertical limb of the T-piece.

Other Types.—There have been many modifications of this apparatus employing essentially the same method of regulation and differing only in minor details of construction.

Bunsen's, Kemp's and Münke's regulators are in reality of the nature of air-thermometers, and act by the expansion and contraction of air, which raises or lowers respectively a column of mercury; this in its turn results in the occlusion or opening of the gas aperture. Such forms, however, are subject to the influence of barometric pressure and an alteration of 0.5 in. of the barometer column may result in the variation of the temperature to as much as 2°.

Lothar Meyer's regulator is described in the *Berichte of the German Chemical Society*, 1883, p. 1089. It is essentially a liquid thermometer, the mercury column being raised by the expansion of a liquid of low boiling-point. The liquid replaces the air in Bunsen's and other similar forms. The boiling-point of this liquid must be below the temperature required as constant.

Toluol-mercury Thermo-regulators.—Novy's thermo-regulator, which is an apparatus of this type, is shown in fig. 10. The bulb (E) is full of toluol which by its expansion forces up the mercury column thus occluding the opening (f). Toluol is used on account of its high coefficient of expansion. Apart from the use of toluol instead of mercury in the bulb the principles of the apparatus are essentially the same as Reichert's. The two ground stoppers (B) and (C) with openings (b, c) and (d) may be rotated so as to regulate both the volume of gas entering the apparatus and the quantity flowing through the by-pass.

Regulators Controlling Electrical Heaters.—Instruments

like the above-described, which incorporate a varying column of mercury, are easily modified to control electrically-heated incubators or water-baths. A platinum wire is fused through the glass so as to make contact with the lower part of the mercury column and the gas inlet tube (f, fig. 10) is replaced by a platinum wire contact. The rising mercury column completes a circuit which operates a small electromagnetic switch breaking the circuit to the heating units. To ensure the satisfactory working of such contacts as these it is necessary to avoid sparking and this may be effected by inserting a condenser (1 microfarad) across the terminals of the spark gap.

Metallic Thermo-regulators.—The solid forms of thermostats are constructed upon the same principle as the compensation balance of a watch or the compensating pendulum of a clock. This depends on the fact that the coefficient of expansion is different for different metals. It therefore results that if two bars of different metals are fastened together along their lengths (fig. 11, Z and ST) with the same rise of temperature one of these will expand or lengthen more than the other. And since both are fastened together and must therefore accommodate themselves within the same linear area, it follows that the compound rod must bend into a curved form, in order that the bar of greater expansion may occupy the surface of greater length, i.e. the convex one. Conversely, when the temperature falls, the greater degree of contraction will be in the same bar, and the surface occupied by it will tend to become the concave one. If, then, one end of this compound rod be fixed and the other free, the latter end will describe a backward and forward movement through the arc of a circle, which will correspond with the oscillations of temperature. This movement can be utilized by means of simple mechanical arrangements, to open or close the stopcock of a gas supply pipe.

In the construction of this type of thermostat it is obvious that the greater the difference in the coefficient of expansion of the two metals used, the larger will be the amplitude of the movement obtained. Steel and zinc are two metals which satisfy this condition. The coefficient of steel is the lowest of all metals and is comparable in its degree with that of glass. Substances which are not metals, such as vulcanite and porcelain, are sometimes used to replace steel, as the substance of low coefficient of expansion.

Roux Thermostat.—The bi-metallic thermostat most commonly employed is one of the two forms designed by Dr. Roux. In one of these forms the compound bar is straight (fig. 11) and in the other it is U-shaped (fig. 12). In the former type the bar itself is enclosed in a tube (T) of metal, the wall of which is perforated. Towards the open end of this tube the gas box or case (C) is fixed. In the U-shaped form it is attached to the outer surface (zinc) of one limb of the bar. The gas box is capable of adjustment with respect to its distance from the bar, by means of a screw (S) and a spiral spring (SP), which moves the box outwards or inwards along a rod (R). This adjustment enables the degree of temperature at which it is desired that the gas shall be cut off to be fixed accurately, and within a certain more or less extended range. The inlet and the outlet pipe are disconnected from each other in the gas box by means of a piston-like rod (P) and valve (V), which slides backwards and forwards in the tubular

FIG. 9.—REICHERT'S THERMO-REGULATOR

FIG. 12.—DR. ROUX'S THERMOSTAT (U-SHAPED BAR)

part (T) of the box, from which the outlet pipe emerges. When the valve (V) rests upon the edge of this box, the gas is completely cut off from passing through the outlet pipe, with the exception of that which passes through an exceedingly small aperture (B), serving as a by-pass. This is just large enough to allow sufficient gas to pass to maintain a small flame. The piston-like rod and valve, when free, is kept pressed outwards by means of a spiral spring. This ensures that the valve shall follow the movements of the compound bar. When this bar bends towards the gas box owing to a fall of temperature, the valve is pushed back away from the orifice and gas in increasing quantity passes through. The temperature of the incubator begins then to rise, and the zinc bar (Z) expanding more than the steel one (ST), the bar bends outwards and the valve once more cuts off the gas supply.

Gas-pressure Regulators.—In order to ensure the accurate working of a thermo-regulator controlling a gas supply it may be necessary to regulate the gas pressure which is sometimes very variable in the mains. Various forms of these regulators are on the market and descriptions of these may be found in catalogues of makers of scientific instruments. It will suffice here if we describe a simple form of regulator (that of R. A. Buddicom) which can be made from material available in most laboratories.

In this regulator (fig. 13) the inlet (I) and outlet (O) gas pipe open into a metal bell (B), the lower and open end of which is immersed beneath water contained in a metal tray (T). The bell is suspended upon the arm of a balance (B) and the other arm is poised by a weight (W). This weight may be made of any convenient material. In the original apparatus a test-tube partially filled with mercury was used. The weight dips into one limb of a U-shaped glass tube (U), which contains mercury. Into the other limb of this tube the gas from the meter enters through a glass tube (G) which is held in position by a well-fitting cork. The internal aperture of the tube (G) is very oblique, and it rests just above the level of the mercury when the instrument is finally adjusted. This adjustment is better made in the morning when the gas pressure in the main is at its lowest. Just above the internal aperture of the tube (G), a lateral tube (L) passes out from the limb of the U and is connected with the inlet pipe (I) of the bell. If the gas pressure rises, the bell (B) is raised and the counter-poising weight (W) is proportionately lowered. This forces the mercury up in the other limb of the U-tube and consequently diminishes the size of the oblique orifice in the tube (G). Some of the gas is thus cut off and the pressure maintained constant. Should the pressure fall, the reverse processes occur, and more gas passes through the orifice of G and consequently to the burner by the outlet tube (O). (For incubators for poultry see POULTRY AND POULTRY FARMING.)

Barlow, *The Art and Method of Hatching and Rearing all Kinds of Domestic Poultry and Game Birds by Steam* (London, 1827); and *Daily Progress of the Chick in the Egg during Hatching in Steam Apparatus* (London, 1824); Walthew, *Artificial Incubation* (London, 1824); William Bucknell, *The Eccleobin. A Treatise on Artificial Incubation*, in 2 parts (published by the author, London, 1830); T. Christy, Jr., *Hydro-Incubation* (London, 1877); L. Wright, *The Book of Poultry* (2nd ed. London, 1893); A. Forget, *L'Aviculture et l'incubation artificielle* (Paris, 1896); J. H. Sutcliffe, *Incubators and their Management* (London, 1896); H. H. Stoddard, *The New Egg Farm* (New York, 1900); Edward Brown, *Poultry Keeping as an Industry* (5th ed., 1904); F. J. M. Page, "A Simple Form of Gas Regulator," *Journ. Chem. Soc.* i. 24 (London, 1876); V. Babes, "Über einige Apparate zur Bacterienuntersuchung," *Centralblatt für Bacteriologie*, iv. (1888); T. Hüppe, *Methoden der Bacterienforschungen* (Berlin, 1889). For further details of bacteriological incubators and accessories see catalogues of Gallenkamp, Baird & Tatlock, Hearson of London, and of the Cambridge Scientific Instrument Company, Cambridge; of P. Lequeux of Paris; and of F. & M. Lautenschläger of Berlin. Those of Lequeux and of the Cambridge Company are particularly useful, as in many instances they give a scientific explanation of the principles upon which the construction of the various pieces of apparatus is based. (G. P. M.; S. L. B.)

INCUBUS, the name given in the middle ages to a male demon which was supposed to haunt women in their sleep, and to whose visits the birth of witches and demons was attributed. The word

is a late Latin derivation (Augustine, *Civ. Dei*, 15. 23) of the classical *incubare*, to lie upon. The female counterparts of these demons, whose temptation of monks and other males bulked so large in the legends of the 11th and 12th centuries, were known as *succubae*. In modern times the word has come to be generally used of an oppressive person or thing.

INCUMBENT, a general term for the holder (rector, vicar, curate in charge) of an ecclesiastical benefice (see **BENEFICE**). In Scotland the title is generally confined to clergy of the Episcopal Church.

INCUNABULA, a Latin neuter-plural meaning "swaddling-clothes," a "cradle," "birthplace," and so the beginning of anything, now curiously specialized to denote books printed in the 15th century. Its use in this sense may have originated with the title of the first separately published list of 15th century books, Cornelius a Beughem's *Incunabula typographiae* (Amsterdam, 1688). The word is generally recognized all over Europe and has produced vernacular forms such as the French *incunables*, German *Incunabeln* (Wiegendrucke), Italian *incunaboli*, and the anglicized form *incunables* is now frequently used. Despite the rapid development of printing in some centres as compared with others, the attractions of a round date have caused the word to be applied to all books produced before the close of the year 1500 and to these alone. The earliest important catalogues of them were (i.) Panzer's *Annales typographici ab artis inventae origine ad annum MD.*, printed in five volumes at Nuremberg in 1793 and subsequently in 1803 carried on to 1536 in six additional volumes; (ii.) Hain's *Repertorium bibliographicum in quo libri omnes ab arte typographica inventa usque ad annum MD. typis expressi ordine alphabetico vel simpliciter enumerantur vel accuratius recensentur* (Stuttgart, 1826–38). In Panzer's *Annales* the first principle of division is that of the alphabetical order of the Latin names of towns in which incunabula were printed, the books being arranged under the towns by the years of publication. In Hain's *Repertorium* the books are arranged under their authors' names, and in 1891 an invaluable index of printers was added by Konrad Burger. In 1898 Robert Proctor published an *Index to the Early Printed Books in the British Museum: from the invention of printing to the year MD., with notes of those in the Bodleian Library*. In this work the books were arranged as far as possible chronologically under their printers, the printers chronologically under the towns in which they worked, and the towns and countries chronologically in the order in which printing was introduced into them, the total number of books registered being nearly 10,000. After Proctor's premature death in 1903, the trustees of the British Museum ordered a full dress catalogue of its incunabula to be prepared, and of this five volumes have been issued, comprising Germany (including Austria and German speaking Switzerland), Rome and Venice. In France Mlle. Pellechet in 1897 began a *Catalogue général des incunables des bibliothèques publiques de France*, which was continued by M. Louis Polain but stopped in the middle of G. In Germany after 21 years of preparation the first volume of a *Gesamtkatalog der Wiegendrucke* was published in 1925.

In any attempt to estimate the extent to which the incunabula still in existence represent the total output of the 15th century presses a sharp distinction must be drawn between the weightier and the more ephemeral literature. Owing to the great religious and intellectual upheaval in the 16th century much of the literature previously current went out of date, while the cumbrous early editions of books still read were superseded by handier ones. Before this happened the heavier works had found their way into countless libraries and here they reposed peacefully, only sharing the fate of the libraries themselves when these were pillaged, or, by a happier fortune, amalgamated with other collections in a larger library. The considerable number of copies of many books for whose preservation no special reason can be found encourages a belief that the proportion of serious works now completely lost is remarkably low, except in the case of books of devotion whose honourable destiny was to be worn to pieces by devout fingers. On the other hand, of the lighter literature in book-form, the cheap romances and catchpenny literature of all kinds, the destruction

has been very great. Most of the broadsides and single sheets generally which have escaped have done so only by virtue of the 16th century custom of using waste of this kind as a substitute for wooden boards to stiffen bindings. Excluding these broadsides, etc., the total output of the 15th century presses in book form is not likely to have exceeded 40,000 editions. As to the size of the editions we know that the earliest printers at Rome favoured 225 copies, those at Venice 300. By the end of the century these numbers had increased, but the soft metal in use then for types probably were badly enough to keep down the size of editions, and an average of 500 copies, giving a possible total of 20 million books put on the European market during the 15th century, is probably as near an estimate as can be made.

Types as Evidence.—Very many incunabula contain no information as to when, where or by whom they were printed, but the individuality of most of the early types as compared with modern ones has enabled typographical detectives (of whom Robert Proctor, who died in 1903, was by far the greatest) to track most of them down. To facilitate this work many volumes of facsimiles have been published, the most important being K. Burger's *Monumenta Germaniae et Italiae Typographica* (1892, etc.), J. W. Holtrop's *Monuments typographiques des Pays-Bas* (1868), O. Thierry-Poux's *Premiers monuments de l'imprimerie en France au XV^e siècle* (1890), K. Haebler's *Typographie ibérique du quinzième siècle* (1901) and Gordon Duff's *Early English Printing* (1896), the publications of the Type Facsimile Society (1700, etc.) and the *Woolley Facsimiles*, a collection of 500 photographs, privately printed by George Dunn.

In his *Index to the Early Printed Books at the British Museum* Proctor enumerated and described all the known types used by each printer, and his descriptions have been usefully extended and made more precise by Dr. Haebler in his *Typenrepertorium der Wiegendrucke* (1905, etc.). With the aid of these descriptions and of the facsimiles already mentioned it is usually possible to assign a newly discovered book with some certainty to the press from which it was issued and to fix within narrow limits the date at which it was finished.

The total number still extant of incunabula printed in England is about 360, of which Caxton produced nearly 100. Of the 10,000 different incunabula which the British Museum and Bodleian Library owned between them in 1898, about 4,100 are Italian, 3,400 German, 1,000 French, 700 from the Netherlands, 400 from Switzerland, 150 from Spain and Portugal, 50 from other parts of the continent of Europe and 200 English, the proportion of these last to the total known being about doubled by the special zeal for collecting them. The celebration in 1640 of the second centenary (as it was considered) of the invention of printing may be taken as the date from which incunabula began to be collected for their own sake, apart from their literary interest, and the publication of Beughe's *Incunabula typographiae* in 1688 marks the increased attention paid to them. But up to the end of the 17th century Caxton's could still be bought for a few shillings. The third centenary of the invention of printing in 1740 again stimulated enthusiasm, and by the end of the 18th century the really early books were eagerly competed for. Interest in books of the last 10 or 15 years of the century is a much more modern development, but with the considerable literature which has grown up round the subject is not likely to be easily checked.

The chief collections of incunabula are those of the Bibliothèque Nationale at Paris, Royal library, Munich, and British Museum, London, the number of separate editions in each library exceeding 9,000 with numerous duplicates. The number of separate editions at the Bodleian Library is about 5,000. Other important collections are at the University library, Cambridge, and the John Rylands library, Manchester, the latter being based on the famous Althorp library formed by Earl Spencer (see *BOOK-COLLECTING*). A census of 15th-century books owned in America, compiled by a committee of the Bibliographical Society of America, published in 1919, enumerated over 13,200 copies of some 6,640 different editions. The chief collections are in the Pierpont Morgan library, New York, the Annmary Brown Memorial, Providence, R.I., the Henry Huntington library, San Gabriel, Calif.,

and the library of Congress at Washington.

(A. W. P.)

INDABA, a Zulu-Bantu word, formed from the inflexional prefix *in* and *daba*, business, news, for an important conference held by the "indunas" or principal men of the Kafir (Zulu-Xosa) tribes of South Africa.

INDAZOLES (BENZOPYRAZOLES), in chemistry, are crystalline, feebly basic organic compounds. Indazole itself has formula (I.) and is prepared by warming an aqueous solution of *o*-toluenediazonium chloride (see DIAZO COMPOUNDS). It

is a crystalline solid melting at 146° C (boiling point, 270° C). This ring formation is exhibited only by diazonium salts having a methyl group adjacent to the diazo-radical. A series of isomeric compounds, *isoidazoles*, is known; the acetyl derivative of the simplest member (formula II.) is made by warming *o*-aminobenzaldoxime with acetic anhydride (see PYRAZOLES).

INDEMNITY, in law, an undertaking, either express or implied, to compensate another for loss or damage, or for trouble or expense incurred; also the sum so paid (see COMPENSATION; CONTRACT; and INSURANCE: *Marine*). An act of indemnity is a statute passed for the purpose either of relieving persons from disabilities and penalties to which they have rendered themselves liable or to make legal transactions which, when they took place, were illegal. An act or bill of indemnity used to be passed every session by the English parliament for the relief of those who had unwittingly neglected to qualify themselves in certain respects for the holding of offices, etc., as, for example, justices, without taking the necessary oaths. The Promissory Oaths Act 1868 rendered this unnecessary. Acts are frequently passed to provide for meeting unforeseen but necessary expenditure incurred in emergencies in the service of the State.

In the United States acts of Congress and of the state legislatures and municipal councils generally, compensating corporations or individuals for damages or expenses incurred for the benefit of the public or the government, are generally termed acts of "relief."

INDENE, a hydrocarbon found in the fraction of the coal tar distillate (see COAL TAR) boiling between 176° and 182° C and isolated from this material by means of the picrate (m.p. 98° C). It is a colourless mobile liquid boiling at 179.5–180.5° C with a specific gravity 1.04 at 15° C. Its chemical formula is C₉H₈, and its constitution (II.) may be deduced from its behaviour on oxidation and reduction. The former process gives phthalic acid (I.), the latter hydrindene or indane (III.), an oil, b.p. 176° C.

Indene rapidly absorbs oxygen from air, and polymerizes to a resin utilizable in lacquers and varnishes.

INDENT, in commerce, an order for goods. The derivation is from Lat. *indentare*, to bite a bit out, hole, to notch. The term is more usually employed in foreign than in home trade. An indent is fully detailed to prevent error, and gives full instructions as to quality, pattern or design, price, exchange, packing, marks and shipment.

INDENTURE, a law term for a special form of deed executed between two or more parties, and having counterparts or copies equal to the number of parties. These copies were all drawn on one piece of vellum or paper divided by a toothed or "indented" line. The copies when separated along this waved line could then be identified as "tallies" when brought together. Deeds executed by one party only had a smooth or "polled" edge, whence the name "deed poll." By the Real Property Act 1845, s. 5, all deeds purporting to be "indentures" have the

effect of an "indenture," even though the indented line be absent. The name "chirograph" was also early applied to such a form of deed, and the word itself was often written along the indented line (see further DEED). The term "indenture" is now used generally of any sealed agreement between two or more parties, and specifically of a contract of apprenticeship, whence the phrase "to take up one's indentures," on completion of the term, and also of a contract by labourers to serve in a foreign country or colony (see COOLIE). In the United States indenture is used generally as a term meaning a conveyance.

INDEPENDENCE, a city in the coal, oil and gas belt of south-eastern Kansas, U.S.A., on the Verdigris river; the county seat of Montgomery county. It is on Federal highway 75, and is served by the Missouri Pacific and the Santa Fe railways. The population was 10,900 in 1925 (State census), and was estimated locally at 15,000 in 1928. It is the supply and shipping point for a rich agricultural district, and for the oil and gas fields near by, and is the headquarters of leading oil companies of the mid-continent field. Its manufactures include flour, sash and doors, oil-field machinery, revolving doors and vitrified and pressed brick. The city was founded and incorporated in 1869.

INDEPENDENCE, a city of Missouri, U.S.A., 10m. E. of Kansas City and 3m. S. of the Missouri river, at an altitude of 1,000ft.; the county seat of Jackson county. It is served by the Chicago and Alton, the Kansas City Southern and the Missouri Pacific railways. The population was 11,686 in 1920 (88% native white) and was estimated at 12,720 in 1925. There are various manufacturing industries, with an output in 1925 valued at \$4,231,807. Independence was laid out and chosen as the county seat in 1827, and was chartered as a city in 1849. In 1831 Joseph Smith selected a tract here to be the site of the New Jerusalem, and was followed in 1832 by some 1,500 Mormons from Ohio, but they were not welcome to the "Gentile" inhabitants, and in 1833 they were driven out. In 1867-69 a few families belonging to the Reorganized Church of Jesus Christ of Latter Day Saints (monogamists) settled here, and by 1881 they had built a church. In 1907 a number of Mormons from Utah came to Independence, moving the headquarters of the "Central States' Mission" from Kansas City, and establishing a publication office. After 1831, until its river landing was destroyed by flood in 1844, Independence was headquarters of the wagon-trains starting west over the Santa Fe, the Old Salt Lake and the Oregon trails.

INDEPENDENCE, DECLARATION OF: see DECLARATION OF INDEPENDENCE.

INDEPENDENTS, in religion, a name used in the 17th century for those holding to the autonomy of each several church or congregation, hence otherwise known as Congregationalists. (See CONGREGATIONALISM.)

INDETERMINATE EQUATIONS: see DIOPHANTINE EQUATIONS.

INDEX, a word that may be understood either as a table of references to a book or, generally, as an indicator of the position of information on any given subject. The classical Latin word *index* denoted a discoverer or informer, a catalogue, an inscription or a book-title, and the fore or index-finger. Cicero also used the word for the table of contents. So also Shakespeare (*Troilus and Cressida*, i. 3). Table was the usual English word, and index was not thoroughly naturalized until the beginning of the 17th century.

In making an index the headings that the reader is most likely to seek must be selected; cross references should not be spared. The index should not be broken up into several alphabets (though this is often done, as into indexes of places, of persons and of subjects). The arrangement may be chronological, alphabetical or classified, but confusion will be caused by combining the three systems. The alphabetical arrangement is so simple, that it has largely superseded other systems. Every endeavour should be made to print an index clearly. In old indexes the indexed word was not brought to the front, but was left in its place in the sentence; but in modern times there has been a great advance in indexing, especially since the foundation in 1877 in England of the Index Society; and the growth of great libraries has given a stimu-

lus to this aid to research. Not only has it become almost a *sine qua non* that any good book must have its own index, but the art of indexing has been applied to great composite works such as the *Encyclopædia Britannica*, to scientific periodicals or groups of periodicals (as in *Index Medicus*), to newspapers like the London and New York *Times*, and to the cataloguing of great libraries themselves. The work in these more elaborate cases has been enormously facilitated by the modern card-indexes, of American origin. The subject indexes of the Library of Congress, of the British Museum and of the London library have much advanced the art. The (British) Association of Special Libraries and Information Bureaux proposes to form a panel of indexers of scientific periodicals. (See also BIBLIOGRAPHY.) The American Library Association has also done notable work.

See H. B. Wheatley, *How to make an Index* (1902), and A. L. Clarke, *Manual of Practical Indexing* (1905); G. E. Brown, *Indexing* (1921); G. S. Fulcher, *Indexing of Scientific Articles* (1922); I. Warren, *Filing and Indexing with Business Procedure* (1924); M. T. Wheeler, *Indexing* (1923).

INDEX LIBRORUM PROHIBITORUM, the title of the official list of those books which on doctrinal or moral grounds the Roman Catholic Church authoritatively forbids the members of its communion to read or to possess, irrespective of works forbidden by the general rules on the subject. The earliest known instance of a list of proscribed books being issued with the authority of a bishop of Rome is the *Notitia librorum apocryphorum qui non recipiuntur*, the first redaction of which, by Pope Gelasius (494), was subsequently amplified on several occasions. The document is for the most part an enumeration of apocryphal gospels and acts. One of the functions of the Inquisition when it was established was to exercise a rigid censorship over books put in circulation. The majority of the condemnations were at that time of a specially theological character. With the discovery of the art of printing, and the wide and cheap diffusion of all sorts of books which ensued, the need for new precautions against heresy and immorality in literature made itself felt; more than one pope (Sixtus IV. in 1479 and Alexander VI. in 1501) gave special directions regarding the growing freedom of the printing press, and in 1515 the Lateran council attempted to forbid the printing of any book without previous examination by the ecclesiastical authority. The Council of Trent in its fourth session, April 1546, forbade the sale or possession of any anonymous religious book which had not previously been seen and approved by the ordinary; in the same year the university of Louvain, at the command of Charles V., prepared an "Index" of pernicious and forbidden books, a second edition of which appeared in 1550. In 1557, and again in 1559, Pope Paul IV., through the Inquisition at Rome, published what may be regarded as the first Roman *Index* in the modern ecclesiastical use of that term (*Index auctorum et librorum qui tanquam hæretici aut suspecti aut perversi ab Officio S. R. Inquisitionis reprobantur et in universa Christiana republica interdicuntur*). In this we find the three classes which were to be maintained in the Trent *Index*: authors condemned with all their writings; prohibited books, the authors of which are known; pernicious books by anonymous authors. At the 18th session of the Council of Trent (February 1562), in consideration of the great increase in the number of suspect and pernicious books, and also of the inefficacy of the many previous "censures" which had proceeded from the provinces and from Rome itself, a commission was appointed to inquire into these "censures," and to consider what ought to be done in the circumstances. The result of its labours was handed over to the pope to deal with as he should think proper. In the following March accordingly were published, with papal approval, the *Index librorum prohibitorum*, which continued to be reprinted and brought down to date, and the "Ten Rules" which regulated the matter until the pontificate of Leo XIII. (1897). The business of condemning pernicious books and of correcting the *Index* to date has been since the time of Pope Sixtus V. in the hands of the "Congregation of the Index," which consists of several cardinals, and more or less numerous "consultors" and "examiners of books."

With the alteration of social conditions, however, the Rules of Trent ceased to be entirely applicable. Their application to publications which had no concern with morals or religion was no longer conceivable; and, finally, the penalties called for modification. Already, at the Vatican Council, several bishops had submitted requests for a reform of the Index, but the Council was not able to deal with the question. The reform was accomplished by Leo XIII., who, on the 25th of January 1897, published the constitution *Officiorum*, in 49 articles. In this constitution, although the writings of heretics in support of heresy are condemned as before, those of their books which contain nothing against Catholic doctrine or which treat other subjects are permitted. Editions of the text of the Scriptures are permitted for purposes of study; translations of the Bible into the vulgar tongue have to be approved, while those published by non-Catholics are permitted for the use of scholars. Obscene books are forbidden; the classics, however, are authorized for educational purposes. Books and newspapers which outrage God and sacred things, which propagate magic and superstition, or which are pernicious to society are forbidden. Permissions to read prohibited books are given by the bishop in particular cases, and in the ordinary course by the Congregation of the Index. The constitution then proceeds with the censorship of books. The examination of the books is entrusted to censors, who have to study them without prejudice; if their report is favourable, the bishop gives the *imprimatur*. All books concerned with the religious sciences and with ethics are submitted to preliminary censorship, and in addition to this ecclesiastics have to obtain a personal authorization for all their books and for the acceptance of the editorship of a periodical. The penalty of excommunication *ipso facto* is only maintained for reading books written by heretics or apostates in defence of heresy, or books condemned by name under pain of excommunication by pontifical letters. The constitution also prescribed a revision of the catalogue of the Index. The new Index, which omits works anterior to 1600 as well as a great number of others included in the old catalogue, appeared in 1900. The encyclical *Pascendi* of Pius X. (8th September 1907) made it obligatory for periodicals amenable to the ecclesiastical authority to be submitted to a censor for report.

BIBLIOGRAPHY.—See J. Hilgers, art. "Index" in the *Catholic Encyclopedia*, and *Der Index der verbotenen Bücher*, 1899; T. Hurley, *Commentary on the present Index Legislation*, 1908; H. Reusch, *Der Index der verbotenen Bücher* (1883); A. Arndt, *De Libris prohibitis commentarii* (1895); A. Boudinhon, *La Nouvelle Législation de l'index* (1899).

INDEX NUMBERS. The phrase index number is sometimes applied to any series in which a chosen term is written as 100 and the other terms expressed as percentages of it. The earlier and more general use is, however, consonant with the following definitions: "An index number [is] a number adapted by its variations to indicate the increase or decrease of a magnitude not susceptible of accurate measurement" (Edgeworth, *Economic Journal*, 1925, p. 379); "index numbers are used to measure the change in some quantity which we cannot observe directly, which we know to have a definite influence on many other quantities which we can so observe, tending to increase all or diminish all, while this influence is concealed by the action of many causes affecting the separate quantities in different ways" (Bowley, *Elements of Statistics*, 1920, p. 196). Thus index numbers are applied to the measurement of the general movement of prices, cost of living, wages, production, consumption, employment, etc.

The data from which index numbers are formed consist of records of particular quantities at two or more dates or places and information about the relative importance of these quantities in a general measurement. In constructing an index number to measure the movement of any defined magnitude it is necessary to decide on the choice of the separate quantities, on their relative importance, on the period or place to be taken as base, and on the formula of compilation. Thus, in the *Statist* index number the objective is the measurement of the change of wholesale prices in the United Kingdom; 45 commodities are selected and regarded as of equal importance, the period 1867-77 is taken as base, the average price in that period of each commodity is equated to

100, the terms in each series of prices are expressed as percentages of that average ("price-relatives"), and the simple average of the 45 relatives in any year forms the index number for that year.

A distinction is drawn, but not by all writers, between two classes of index numbers: (a) where, as in the definitions quoted above, the object is to measure the movements of a magnitude without specific reference to any pre-determined application, e.g., the purchasing power of money in general ("indice monétaire") as conceived by Jevons, *The Variation of Prices and the Value of Currency since 1782* (1865); (b) where the measurement is to be applied to a defined group, e.g., the changes in the cost of a quantitative standard, such as is used in a cost of living index ("indice budgétaire"). Many index numbers, however, are intermediate between these classes, and much of the analysis of the form and content of the numbers is appropriate to both. Thus, in all cases of price measurement, only those commodities can be included which are measurable in a defined and unchanged unit, and for which the price can be ascertained, and (unless the geometric mean is used) a base period in which each price is equated to 100 must always be selected.

PURCHASING POWER

(a) In the measurement of the purchasing power of money in general it is argued that the prices of all commodities, not subject to regulation or monopoly, are equally significant. Theoretically the problem is one of pure sampling, and the precision of the result in any year is directly proportional to the square root of the number of independent terms included and inversely proportional to the mean dispersion of these terms from their average in that year. In practice, the terms are not completely independent, for the prices of related commodities influence one another, and the precision is thus reduced. Also, the greater the interval from the base year, the greater tends to be the dispersion and the smaller the precision. In periods when prices are changing rapidly, as in the years 1914 to 1923, the dispersion is usually considerable and the measurement loses accuracy.

There are three types of averages applicable to price-relatives: their arithmetic mean as described above for the *Statist* index number; the geometric mean of the same numbers, that is the n th root of their product if there are n commodities; and the harmonic mean, which is the reciprocal of the arithmetic mean of the reciprocals. Thus, for two commodities whose prices were 6d. and 10d. in the base year, and 1s. and 2s. 1d. in any other year, the price-relatives are 200 and 250, their A.M. is 225, their G.M. is $\sqrt{200 \times 250} = 223.6$, their H.M. is $1 \div \frac{1}{2}(\frac{1}{200} + \frac{1}{250}) = 222.2$. If the latter year is taken as 100, the relatives in the original base year are 50 and 40, the A.M. is 45, and $45:100 = 100:222.2$. The H.M. of the "forward" relatives gives the same measurement as the A.M. of the "backward" relatives; or, if the comparison is between two places the H.M. of the relatives when the first is taken as base gives the same measurement as the A.M. when the second is so taken.

A general change in the relation of currency to its use tends to affect all prices in the same proportion, and "if other disturbing causes may be considered proportional to the ratio of change of price they produce in one or more commodities, then all the individual variations of prices will be correctly balanced off against each other in the Geometric Mean" (Jevons, *Investigations in Currency and Finance*, 1884, pp. 121-122; see also Bowley, *Economic Journal*, 1921, p. 202). The Geometric Mean is therefore considered appropriate to this problem. It has the advantage that it gives less importance to extreme measurements than does the Arithmetic Mean. It has the further advantage that the comparison by its use of any two years is independent of the choice of the base year (see below).

CHANGE IN A FIXED AGGREGATE

(b) The method generally used in the more objective problem of measuring the change of cost of a fixed aggregate of goods is as follows: the quantities of defined commodities which are produced or consumed in a year, or exported or imported, or are purchased in a week by a family; are estimated and the prices per unit are

ascertained in a base year or period and also in the year to which the measurement is to refer. This budget of quantities is valued at the base year prices and again at the prices of the year in question; the latter total expressed as a percentage of the first gives the required index number. The computation is often effected by writing down the relative expenditure (quantity \times price) on each commodity in the base year, applying to each the percentage that its price in the second year forms of that in the first, and adding the products. This sum (divided by the total of the base year's relative expenditures) gives the same index number as before. Cost of living index numbers are computed by this method. In this form the index number appears as a "weighted average," where the weights are the relative expenditures and the things weighted are the price-relatives. From the theory of weighted averages it is known that considerable roughness in the weights has little effect on the result. It may also be regarded as an average of price-relatives which form a sample of a larger group than that included, and therefore—as under (a)—its precision depends on the square root of the number of independent relatives and, inversely, on their dispersion about their average.

The weakness of this method is that, when we make a comparison between two years or two places, the relative expenditures generally differ and each scheme of expenditure appears to have an equal claim to be included. This difficulty may be met theoretically by computing the index twice, first with the expenditures in year or place A and then with those in B and averaging the result. For comparison between places this method is applied; but it is seldom that the necessary "weights" can be obtained for more than one year, and till there is a further census of production or a new collection of working class budgets the double computation cannot be made. Further, if the weights are available for three years or places, A, B and C, the index for B in reference to A multiplied by that for C in reference to B does not by any weighted average formula give that for C in reference to A ($\div 100$), as it should. This so-called "condition transitive" is not satisfied by any formula that is symmetrical with regard to weights. The algebra of the method is as follows:—

Write ${}_aQ_1, {}_aQ_2, \dots$ and ${}_aP_1, {}_aP_2, \dots$ for quantities and prices in A, and ${}_bQ_1, {}_bQ_2, \dots, {}_bP_1, {}_bP_2, \dots$ in B. The "forward" index number is $I_a = 100 \frac{\sum {}_aQ_1 \cdot {}_bP_1}{\sum {}_aQ_1 \cdot {}_aP_1}$ and the "backward" index number is $I_b = 100 \frac{\sum {}_bQ_1 \cdot {}_aP_1}{\sum {}_bQ_1 \cdot {}_bP_1}$. The Geometric Mean $\sqrt{I_a \times I_b}$ is Prof. Irving Fisher's "Ideal index number" (*The Making of Index Numbers*, 1922, p. 220). The arithmetic average, $\frac{1}{2}(I_a + I_b)$ and the form $I_2 = 100 \frac{\sum \frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_bP_1}{\sum \frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_aP_1}$, may be conveniently used. The three forms of average may be expected to give nearly identical results. I_2 , in which the quantities at the two dates are averaged, is perhaps the simplest in idea. Each average lies between I_a and I_b , and is greater than I_a if an increase of prices of a commodity above the general increase from year A to a later year B is correlated with a relative decrease of the quantity purchased, as may be expected if there is a possibility of substitution of one commodity for another without any general change of standard (Bowley, *Statistical Journal*, 1919, pp. 343 seq.).

In their measurement of the change of import or export index prices from year A to the consecutive year B, the Board of Trade uses the formula I_b and for comparison with the next year C

the formula $100 \times \frac{\sum {}_bQ_1 \cdot {}_bP_1}{\sum {}_bQ_1 \cdot {}_aP_1} \times \frac{\sum {}_cQ_1 \cdot {}_aP_1}{\sum {}_cQ_1 \cdot {}_bP_1}$ which does not equal

$100 \frac{\sum {}_cQ_1 \cdot {}_aP_1}{\sum {}_cQ_1 \cdot {}_bP_1}$ obtained by direct re-valuation of the C quantities by the A prices and, if there is a very rapid change of quantities and prices, may differ considerably from it. This is an example of the "step-by-step" or "chain" method of index numbers. Note

that from A to B, $100 \frac{\sum {}_bQ_1 \cdot {}_aP_1}{\sum {}_aQ_1 \cdot {}_aP_1}$ is an index number of quantity

of trade (prices constant), and $100 \frac{\sum {}_bQ_1 \cdot {}_bP_1}{\sum {}_aQ_1 \cdot {}_aP_1}$ is the index number of value of trade. The product of these measurements of price and quantity is the index of value ($\times 100$).

Since no form of index number satisfies all the conditions which

can properly be laid down (see e.g., Gini, in *Metron*, 1924, pp. 81 and 134), we must select in each case the form most suited for the particular purpose in hand (regard being had to the data available) and it follows that we can only expect precision when different relevant forms give approximately the same result, for which the conditions are that the dispersion of prices from their average should be small and the number of constituent elements should be considerable. See COST OF LIVING: PRICES.

(A. L. B.)

INDEX SYSTEM: see OFFICE APPLIANCES.

INDIA, a great country and empire of Asia under British rule, inhabited by a congeries of different races, speaking upwards of 200 different languages. The whole Indian empire, including Burma, has an area of 1,805,000 sq.m., and had in 1928 a population of 319 millions, being about equal to the area and population of the whole of Europe without Russia. Gibbon's estimate for all the races and nations which obeyed imperial Rome was 120 millions.

The Indians can scarcely be said to have a word of their own by which to express their common country. In Sanskrit, it would be called "Bharata-varsha," from Bharata, a legendary monarch of the Lunar line; but Sanskrit is no more the vernacular of India than Latin is of Europe. The name "Hindustan," which was at one time adopted by European geographers, applies properly only to that portion of the peninsula lying north of the Vindhya mountains, or yet more strictly to the upper basin of the Ganges where Hindi is the spoken language. The "East Indies" is an old-fashioned and inaccurate phrase, dating from the dawn of maritime discovery. "India," a word derived through the Greeks from the Persicized form of the Sanskrit *sindhu*, a "river," pre-eminently the Indus, has become familiar since the British acquired the country, and is now officially recognized in the imperial title of the sovereign.

THE COUNTRY

Position and Shape.—India, as thus defined, is the middle of the three irregularly shaped peninsulas which jut out southwards from the mainland of Asia. Its form is that of a great triangle, with its base resting upon the Himalayan range and its apex running far into the ocean. It extends from the 8th to the 37th degree of north latitude; that is to say, from the hottest

BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIP COMPANY.

THE VICTORIA TERMINUS OF THE GREAT INDIAN PACIFIC PENINSULA RAILWAY, IN BOMBAY CITY, CAPITAL OF THE BOMBAY PRESIDENCY

regions of the equator to far within the temperate zone. The length of India from north to south, and its greatest breadth from east to west, are both about 1,900 m.; but the triangle tapers with a pear-shaped curve to a point at Cape Comorin, its southern extremity. To this compact dominion the British have added Burma, the strip of country on the eastern shores of the Bay of Bengal. But on the other hand the adjacent island of Ceylon has been administratively severed and placed under the Colonial Office. Two groups of islands in the Bay of Bengal, the Andamans and the Nicobars; one group in the Arabian Sea, the Laccadives; and the outlying station of Aden at the mouth of the Red Sea, with Perim, and protectorates over the island of

Sokotra, along the southern coast of Arabia and in the Persian Gulf, are all politically included within the Indian empire; while on the coast of the peninsula itself, small Portuguese and French settlements break the continuous line of British territory.

Boundaries.—India is shut off from the rest of Asia on the north by a vast mountainous region, known in the aggregate as the Himalayas, amid which lie the independent states of Nepal and Bhutan, with the great table-land of Tibet behind. From the rest of the world it is severed by tropical oceans, except where Burma marches, in a confused succession of little explored ranges, with the kingdom of Siam. The empire included within these boundaries is rich in varieties of scenery and climate, from the highest mountains in the world to vast river deltas raised only a few inches above the level of the sea. It practically forms a continent rather than a country, divisible into three separate and well-defined tracts.

Himalayas.—The first of the three regions is the Himalaya mountains and their offshoots to the southward, comprising a system of stupendous ranges, the loftiest in the world. They extend in the shape of a scimitar, with its edge facing southwards, for a distance of 1,500 m. along the northern frontier of India. At the north-eastern angle of that frontier, the Dihang river, the connecting link between the Tsampo of Tibet and the Brahmaputra of Assam, bursts through the main axis of the range. At the opposite or north-western angle, the Indus in like manner pierces the Himalayas, and turns southwards on its course through the Punjab. Ancient and well-known trade routes exist, by means of which merchandise from the Punjab finds its way over heights of 18,000 ft. into Eastern Turkestan and Tibet. The Muztagh (Snowy Mountain), the Karakoram (Black Mountain), and the Changchenmo are the most famous of these passes.

The Himalayas not only form a double wall along the north of India, but at both their eastern and western extremities send out ranges to the south, which protect its north-eastern and north-western frontiers. On the north-east, those offshoots form a barrier between the civilized districts of Assam and the wild tribes of Upper Burma. On the opposite or north-western frontier of India, the mountains run down the entire length of the British boundaries from the Himalayas to the sea. As they proceed southwards, their best marked ranges are in turn known as the Safed Koh, the Suliman and the Hala mountains. These massive barriers have peaks of great height, culminating in the Takht-i-Suliman or Throne of Solomon, 11,317 ft. above the level of the sea. But the mountain wall is pierced at the corner where it strikes southwards from the Himalayas by an opening through which the Kabul river flows into India. An adjacent opening, the Khyber Pass, the Kurram Pass to the south of it, the Gomal Pass near Dera Ismail Khan, the Tochi Pass between the two last-named, and the famous Bolan Pass still farther south, furnish the gateways between India and Afghanistan. The Hala, Brahui and Pab mountains, forming the southern hilly offshoots between India and Baluchistan, have a much less elevation.

River Plains.—The wide plains watered by the Himalayan rivers form the second of the three regions of India. They extend from the Bay of Bengal on the east to the Afghan frontier and the Arabian Sea on the west, and contain the richest and most densely crowded provinces of the empire. The vast level tract which thus covers northern India is watered by three distinct river systems. One of these systems takes its rise in the hollow trough beyond the Himalayas, and issues through their western ranges upon the Punjab as the Sutlej and Indus. The second of the three river systems also takes its rise beyond the double wall of the Himalayas, not very far from the sources of the Indus and the Sutlej. It turns, however, almost due east instead of west, enters India at the eastern extremity of the Himalayas, and becomes the Brahmaputra. These rivers collect the drainage of the northern slopes of the Himalayas, and convey it, by long and tortuous although opposite routes, into India. The third river system of northern India receives the drainage of their southern slopes, and eventually unites into the mighty stream of the Ganges.

Southern Table-land.—The third division of India com-

prises the three-sided table-land which covers the southern or more strictly peninsular portion of India. This tract comprises the Central Provinces and Berar, the presidencies of Madras and Bombay, and also Hyderabad, Mysore and other states.

Its northern side rests on confused ranges, running with a general direction of east to west, and known in the aggregate as the Vindhya mountains. Guarding the flanks of this tumbled mass stand two peaks sacred to the mysteries of the Jain religion, Mount Abu on the extreme west, and Mount Parasnath on the extreme east, with a succession of ranges stretching 800 m. between. The various ranges of the Vindhyas, from 1,500 to over 4,000 ft. high, form, as it were, the northern wall and buttresses which support the central table-land. Though now pierced by road and railway, they stood in former times as a barrier of mountain and jungle between northern and southern India, and formed one of the main obstructions to welding the whole into an empire.

Ghats.—The other two sides of the elevated southern triangle are known as the Eastern and Western Ghats. These start southwards from the extremities of the Vindhya system, and run along the eastern and western coasts of India. The Eastern Ghats stretch in fragmentary spurs and ranges down the Madras presidency, here and there receding inland and leaving broad level tracts between their base and the coast. The Western Ghats form the great sea-wall of the Bombay presidency, with only a narrow strip between them and the shore. The Eastern Ghats have an average elevation of 1,500 feet. The Western Ghats ascend more abruptly from the sea to an average height of about 3,000 ft. with peaks up to 4,700 along the Bombay coast, rising to 7,000 and even 8,760 (Dodabetta Peak) in the upheaved angle which they unite to form with the Eastern Ghats, towards their southern extremity. The inner triangular plateau thus enclosed lies from 1,000 to 3,000 ft. above the level of the sea. But it is dotted with peaks and seamed with ranges exceeding 4,000 ft. in height. Its best known hills are the Nilgiris, with the summer capital of Madras, Ootacamund, 7,000 ft. above the sea.

Eastern Ghats.—On the eastern side of India, the Ghats are traversed by a number of broad and easy passages from the Madras coast. Through these openings the rainfall of the southern half of the inner plateau reaches the sea. The drainage from the northern or Vindhyan edge of the three-sided table-land falls into the Ganges. The Nerbudda and Tapti carry the rainfall of the southern slopes of the Vindhyas and of the Satpura hills, in almost parallel lines, into the Gulf of Cambay. But from Surat to the furthest south, the Western Ghats form a lofty unbroken barrier between the waters of the central plateau and the Indian Ocean. The drainage has therefore to make its way across India to the eastwards, now turning sharply round projecting ranges, now tumbling down ravines, or rushing along the valleys, until it finally falls into the Bay of Bengal. In this way the three great rivers of the Madras Presidency, viz., the Godavari, the Kistna and the Cauvery, rise in the mountains overhanging the western coast, and traverse the whole breadth of the central table-land before they reach the sea on the eastern shores of India.

Of the three regions of India thus briefly surveyed, the first, or the Himalayas, lies for the most part beyond the British frontier, but a knowledge of it supplies the key to the ethnology and history of India. The second region, or the great river plains in the north, formed the theatre of the ancient race-movements which shaped the civilization and the political destinies of the whole Indian peninsula. The third region, or the triangular table-land in the south differs markedly in its population, languages and traditions from either of the other two divisions. (ME.)

GEOLOGY

Geologically, as well as physically, India consists of three distinct elements—the Himalayas, the Peninsula, and the Indo-Gangetic plain. The relations of the Himalayas to the Peninsula and the essential differences between them are dealt with in the article on Asia, and a more detailed description of the geology of the Himalayas is given elsewhere. The following account deals only with the Indo-Gangetic plain and the Peninsula.

Indo-Gangetic Plain.—The Indo-Gangetic depression is the

fore-deep of the Himalayas, lying between the folded belt which forms the mountain range and the rigid foreland constituted by the Peninsula. It bears the same relation to the Himalayas as the Pacific Deep bears to the island arcs near which they lie, but in these the level is lower and both foreland and fore-deep lie beneath the sea. There can be no doubt, however, that the Himalayan fore-deep itself extends far below sea-level, though since its formation it has been filled up by deposit. In the eastern section of the plain the deposit is chiefly alluvial material brought down from the hills, in the western section wind-blown material plays an important part. Everywhere, except in the neighbourhood of the hills, the deposit is fine-grained, consisting of sands and muds, though *kankar* concretions may sometimes give a pebbly appearance.

No boring has ever reached the base of the alluvium, or has even shown any downward increase in the coarseness of the material. In a boring at Calcutta a bed of peat with wood, about 360 ft. below sea-level, clearly points to subsidence. A boring at Lucknow reached nearly 1,000 ft. below sea-level without any indication of an approach to the bottom of the deposit. Sir Sidney Burrard finds that the deflections of the plumb-line and anomalies of gravity suggest that the loose material filling the Indo-gangetic depression extends to a depth of 40,000 feet. He himself thinks so great a depth is scarcely probable. But the fore-deeps of much less massive mountain arcs reach 20,000 ft. and more, and in comparison with these Sir Sidney Burrard's estimate seems not improbable for the Himalayan fore-deep.

Peninsular India.—The geological history of the Indian Peninsula has been so different from that of Europe that the classification of the strata which is natural in Europe cannot be used in India and an almost entirely different terminology becomes necessary. The grouping, originally proposed by Holland, which is now commonly adopted is as follows:—

Aryan Group	{ Tertiary and Recent Cretaceous and Deccan Trap Gondwana System
Dravidian Group	(Absent in the Peninsula)
Purana Group	{ Vindhyan System Cuddapah System
Vedic or Archaean Group	{ Dharwar System Gneisses and Granites

The term Archaean is here used in the restricted sense in which it is often employed, denoting only the crystalline and schistose rocks of Pre-Cambrian age. The Purana group consists of normal sedimentary deposits which rest unconformably upon the Archaean but which, from the total absence of fossils, are believed to be Pre-Cambrian also, like the Algonkian of North America or the Torridonian of Scotland. The Dravidian group, which is absent in the Peninsula but present in the Himalayas, corresponds approximately with the Palaeozoic up to the Upper Carboniferous. The Gondwana system includes the oldest fossiliferous beds of the Peninsula and ranges from the Upper Carboniferous to the Upper Jurassic.

The Pre-Gondwana rocks (Archaean and Purana groups) form the foundation of the whole Peninsula. Southeast of a line drawn from Goa to Allahabad they occupy most of the surface, the areas covered by the later beds being relatively small. Northwest of this line they are concealed over a wide space by the great outflows of the Deccan Trap, but they reappear at the surface in Bandelkhand and Gujarat. In Southern India appearances suggest that there was an ancient gneissic series, including granitic and other intrusive masses, into which has been infolded a later series of sedimentary and volcanic beds, now for the most part converted into schists. The schistose series is the Dharwar system, which runs in long narrow bands through the gneiss from south-south-east to north-north-west. There has certainly been strong folding in this direction, but the Mysore geologists think that the Dharwar system is the older and that the gneissic rocks have been intruded into it. Farther north, however, where the Dharwar rocks have been less altered and retain their original bedding, they seem to be later than the main body of the gneiss,

though intrusions of later date penetrate both. The gneissic series is in fact a complex of various ages and it has not yet been possible to separate it completely into its several parts.

Rocks of Dharwar type and probably of Dharwar age occur also in the Aravalli Hills, in the Central Provinces and in Western Bengal. The famous "marble rocks" of Jabalpur, for example, are referred to this system. It is interesting to note that while in Southern India the trend of the Dharwar folds is from south-south-east to north-north-west, in the Aravalli Hills it is from south-west to north-east.

The Dharwar rocks form the most highly metalliferous system in India. In Southern India all the most productive gold-bearing quartz veins, including those of the Kolar gold-field, lie within it; while in the Central Provinces and Bengal it includes valuable manganiferous deposits. Iron ore of high quality also occurs at several localities, but is usually too distant from the coalfields to be profitably worked.

The rocks of the Purana group have not been subjected to the intense folding which has affected the Dharwar system and have suffered little from metamorphism. They are mostly sedimentary deposits, such as sandstones, shales and limestones, and rest quite unconformably and often horizontally upon the older rocks. But in spite of their unaltered condition no fossils have been found in them and for this reason they are supposed to be Pre-Cambrian in age. In Southern India the group occurs in the Cuddapah basin and between Belgaum and Kaladgi. It covers a wide area in the Central Provinces and it forms most of the northern border of the Peninsular massif overlooking the Indo-gangetic plain. Several unconformities have been recognised in the group and various local subdivisions have been made; but in the absence of fossils the correlation of rocks in widely separated areas is necessarily open to doubt. Two points of general interest may be noted. In the first place, although both the Cuddapah and the Vindhyan systems are often undisturbed, yet in places the former has been strongly folded. Along the eastern margin of the Cuddapah basin, for example, the Cuddapah beds show strong overfolding and overthrusting towards the east, the trend of the folds being from north to south. If these beds are correctly referred to the Pre-Cambrian there were certainly two great periods of mountain-building in Pre-Cambrian times, separated by a long interval, the first one being post-Dharwar and pre-Cuddapah and the second post-Cuddapah and pre-Vindhyan.

The second point of general interest is that all the most famous diamond deposits of India, such as that of Karnul in S. India and of Pannah in Bandelkhand, belong to the upper Vindhyan system. The diamonds usually occur in sandstone or conglomerate, and have evidently been carried by water in the same way as other pebbles. No diamond-bearing igneous rock like that of Kimberley has been found and the original source from which the diamonds have been derived is unknown, though certain igneous rocks have been suspected.

The Gondwana System.—The Gondwana system is the most important and interesting set of beds in India. Outside the Peninsula, for example in Assam, coal is found chiefly in the Eocene, but in the Peninsula all the principal coal-seams lie in the Lower Gondwana series. The Gondwana beds occur in strips which are let into the foundation of older rock by faults. These strips, which may be continuous or broken, show a close connection with the lines of existing rivers, and probably by their comparative softness determined the courses which the rivers took. There is, for example, a series of Gondwana patches along the Damodar and a more continuous strip roughly parallel to the Mahanadi. These two strips unite into a broad triangular area traversed by the Son. Another strip is associated with the Godavari.

The Gondwana system consists chiefly of sandstones, shales and clays, with seams of coal in the lower division. For the most part the deposits are entirely of terrestrial origin, but in Cutch and at several places along the Coromandel coast marine beds are interstratified towards the top. The fossils found in these marine bands are of Upper Jurassic age. In general, however, plants are the predominant fossils, with reptiles, crustacea and freshwater fish locally. The Lower Gondwana is characterised by

ferns of the *Glossopteris* type and by Equisetaceae, the Upper Gondwana by the prevalence of Cycadaceae. The lowest subdivision of the Gondwana system is known as the Talchir series and near its base is a remarkable clay with striated boulders, now universally admitted to be of glacial origin. In its lithology, fauna and flora the Gondwana system of India is remarkably like the Karroo system of South Africa, and it was this resemblance that led Suess and Neumayr to the conception of "Gondwana Land." It should, however, be pointed out in passing that the *Glossopteris* flora has a much wider distribution than was originally supposed and extends into northern Asia and Russia.

The chief interest of the Indian Cretaceous lies in the evidence that it affords for a former connection between India and South Africa. The marine Cretaceous of the Indian Peninsula belongs entirely to the Upper division of the system. A number of detached outcrops occur along the valley of the Narbada from the town of Bagh in Gwalior, past Baroda, to Wadhwan in Kathiawar. In the south of India there is a Cretaceous area of two or three hundred square miles in Trichinopoly district, and smaller patches near Pondicherry and Viruddhachalam. By far the greater number of species which have been obtained from the Narbada Cretaceous occur also in Europe but only about a third of them have been found in southern India. On the other hand only about a sixth of the numerous species which have been found in the South Indian Cretaceous occur in Europe. Moreover, there are Cretaceous beds in Assam and nearly all the species found there are Southern Indian forms. Finally, many of the Assam and South Indian species occur also in South Africa. Hence it has been concluded that in Upper Cretaceous times the Narbada area lay in a northern sea which stretched into Europe, while Assam and the southeast border of India lay in a southern sea which extended to South Africa. Between these seas a land-mass stretched from Africa to India.

The Deccan Trap.—The Deccan Trap is an extensive series of basaltic lava-flows, with a total thickness of several thousand feet, which covers an area of about 250,000 square miles in the north-western quadrant of the Peninsula. Along the west coast it reaches the sea without any diminution in thickness from about 21° N. to 16° N., and since the lavas are certainly subaerial it is clear that at the time of their eruption the land must have extended much farther to the west than it does now. The flat-topped hills and deep-cut valleys characteristic of the Deccan Trap area are well shown on the route to Bombay either from Calcutta or Madras. In spite of the great extent of these lavas there is very little indication of volcanoes, and it is believed that the eruptions took place from fissures, with little explosive action. The duration of the eruptions cannot be determined with certainty. Probably they began during the later part of the Cretaceous period but may have continued into the Eocene.

The Tertiary beds of the Peninsula are insignificant. Near the west coast there are a few small outcrops in Travancore, Gujarat and Kathiawar, and a more complete sequence in Cutch. On the east coast the Cuddalore series, ranging in age from Eocene to Pliocene, occurs in patches from Orissa to the southern extremity of the Peninsula.

The most interesting of the recent deposits in India is Laterite (*q.v.*) which caps many of the hills and plateaux of the Deccan Trap area and is also found extensively at a lower level both upon the western and the eastern border of the Peninsula. It is a surface formation due to a special type of weathering characteristic of regions where temperature and humidity are sufficiently high. It owes its prominence to the fact that it hardens on exposure and after hardening it often resists erosion more strongly than the rocks on which it rests.

(P. L.A.)

BIBLIOGRAPHY.—The official *Manual of the Geology of India*, Calcutta, is still useful although the latest edition was published in 1893. Geology, by T. H. Holland, Vol. I. of the *Imperial Gazetteer of India* (1907); *Geology of India*, by D. N. Wadia (1926). A general geological map of India, scale 1 in.=32 m., is published by the Geological Survey, last edition 1925.

CLIMATE

1. **Regional.**—The great peninsula of India, with its lofty mountain ranges behind and its extensive seaboard exposed to the

first violence of the winds of two oceans, forms an exceptionally valuable field for the study of meteorological phenomena.

From the gorge of the Indus to that of the Brahmaputra, a distance of 1,400 m., the Himalayas form an unbroken watershed. The average elevation of the Himalaya crest may be taken at not less than 19,000 ft., and therefore equal to the height of the lower half of the atmosphere; and indeed few of the passes are under 16,000 or 17,000 ft. Across this mountain barrier there appears to be a constant flow of air, more active in the day-time than at night, northwards to the arid plateau of Tibet.

At the foot of the great mountain barrier, and separating it from the more ancient land which now forms the highlands of the peninsula, a broad plain, for the most part alluvial, stretches from sea to sea. In the mid-west of this plain is a dry region occupied partly by the alluvial deposits of the Indus and its tributaries and the saline swamps of Cutch, partly by the rolling sands and rocky surface of the desert of Jaisalmer and Bikaner, and the more fertile tracts to the eastward watered by the Luni. Over the greater part of this region rain is of rare occurrence; and not infrequently more than a year passes without a drop falling on the parched surface. On its eastern margin, however, in the neighbourhood of the Aravalli hills, and again in the northern Punjab, rain is more frequent, occurring both in the south-west monsoon and also at the opposite season in the cold weather.

The alluvial plain which lies north of the desert area and is traversed by the Indus and its tributaries passes into that of the Gangetic valley without visible interruption. Up or down this plain, at opposite seasons, sweep the rain-bearing monsoon winds, in a direction at right angles to that of their nominal course. Nearly the whole surface of the Gangetic plain is under cultivation, and it ranks among the most productive as well as the most densely populated regions of the world. The rainfall diminishes from 100 in. in its south-east corner to less than 30 in. at Agra and Delhi, and there is an average difference of from 15 to 25 in. between the northern and southern borders of the plain.

From the Bengal delta at its eastern extremity, two alluvial plains stretch up between the hills which connect the Himalayan system with that of Burma. The first, or the valley of Assam and the Brahmaputra, is long and narrow, bordered on the north by the Himalayas, on the south by the lower plateau of the Garo, Khasi and Naga hills. The other, short and broad, and in great part occupied by swamps, separates the Garo, Khasi and Naga hills from those of Tippera and the Lushai country. The climate of these plains is damp and equable, and the rainfall is prolonged and generally heavy, especially on the southern slopes of the hills.

The peninsula area of India, cut off from the encircling ranges by the broad Indo-Gangetic plain, is divided into two unequal parts by the Vindhyas, an amalgam of several hill systems running almost continuously across the country from west by south to east by north, just south of the Tropic of Cancer. The waters to the north of this watershed drain chiefly into the Nerbudda and the Ganges, those to the south into the Tapti, the Mahanadi, the Godavari and some smaller streams. Together with the two parallel valleys of the Nerbudda and Tapti, which drain the flanks of its western half, this mass of hills gives, at opposite seasons of the year, a decided easterly and westerly direction to the winds of this part of India, and condenses a tolerably copious rainfall during the south-west monsoon.

The peninsula south of the Vindhyas consists chiefly of the triangular plateau of the Deccan, terminating abruptly on the west in the Sahyadri range (Western Ghats), and shelving to the east (Eastern Ghats). This plateau is swept by the south-west monsoon, but not until it has surmounted the western barrier of the Ghats; and hence the rainfall is, as a rule, light at Poona and places similarly situated under the lee of the range, and but moderate over the more easterly parts of the plateau. The rains, however, are prolonged some three or four weeks later than in tracts to the north of the Vindhyas, since they are also brought by the easterly winds which blow from the Bay of Bengal in October and the early part of November, when the recurved southerly wind ceases to blow up the Gangetic valley, and sets towards the south-east coast.

At the junction of the Eastern and Western Ghats rises the bold triangular plateau of the Nilgiris, and to the south of them come the Anamalais, the Palnis, and the hills of Travancore. These ranges are separated from the Nilgiris by a broad depression or pass known as the Palghat Gap, some 25 m. wide, the highest point of which is only 1,500 ft. above the sea. This gap affords a passage to the winds which elsewhere are barred by the hills of the Ghat chain. The country to the east of the gap receives the rainfall of the south-west monsoon. In the strip of low country that fringes the peninsula below the Ghats the rainfall is heavy.

2. **The Seasons.**—Within the boundaries of India almost any extreme of climate that is known to the tropics or the temperate zone can be found. It is influenced from outside by two adjoining areas. On the north, the Himalaya range and the plateau of Afghanistan give it a continental climate; on the south the ocean gives it an oceanic climate. The continental type of weather prevails over almost the whole of India from December to May, and the oceanic type from June to November, thus giving rise to the two great divisions of the year, the dry season or north-east monsoon, and the rainy season or south-west monsoon. India thus becomes the type of a tropical monsoon climate.

The Indian year may be divided into four seasons: the cold season, including the months of January and February; the hot season, comprising the months of March, April and May; the south-west monsoon period, including the months of June, July, August, September and October; and the retreating monsoon period, including the months of November and December. The temperature is nearly constant in southern India the whole year round, but in northern India the variation is very large.

In the cold season the mean temperature averages about 30° F lower in the Punjab than in southern India. In the Punjab, the United Provinces, and northern India generally the climate from November to February resembles that of the Riviera, with a brilliant cloudless sky and cool dry weather. This is the time for the tourist to visit India. The hot season begins about the middle of March, when there is a steady rise in temperature, until the break of the rains in June. In May the highest temperatures are found in Upper Sind, north-west Rajputana, and south-west Punjab. At Jacobabad the thermometer sometimes rises to 125° in the shade.

The south-west monsoon currents usually set in during the first fortnight of June on the Bombay and Bengal coasts, though they linger on their way up-country, and give more or less general rain in every part of India during the next three months. But the distribution of the rainfall is very uneven. Overlooking the Bay of Bengal, where the mountains catch the masses of vapour as it rises off the sea, the rainfall is enormous. At Cherrapunji in the Khasi hills it averages upwards of 500 in. a year. The Bombay monsoon leaves with very little rain a strip 100 to 200 m. in width in the western Deccan parallel with the Ghats, and it is this part of the Deccan, together with the Mysore table-land and the Carnatic, that is most subject to drought. Similarly the Bengal monsoon passes by the Coromandel coast and the Carnatic with an occasional shower, taking a larger volume inland, and abundant rain to Assam and Cachar. The same current also supplies with rain the broad band across India, which includes the Vindhya, Chota Nagpur, the greater part of the Central Provinces and Central India, Orissa and Bengal. Rainfall rapidly diminishes to the north-west from that belt. A branch of the Bombay current blows pretty steadily through Rajputana to the Punjab, carrying some rain to the latter province. But the greater part of north-west India is served as a rule by cyclonic storms between the two currents. In September the force of the monsoon begins rapidly to decline, and in its rear springs up a gentle steady north-east wind, which gradually extends over the Bay of Bengal, and is known as the north-east monsoon. A wind similar in character, but rather more easterly in direction, simultaneously takes possession of the Arabian Sea. The most unhealthy season immediately follows the rains, when malaria is prevalent, especially in northern India. (ME.)

FLORA

British India (including Ceylon and Burma) has not any distinctive botanical features peculiar to itself; its flora is com-

pounded out of those of the adjoining countries. In the mountainous region in the extreme north-west many European and Siberian forms occur, while the north-east displays the influence of Western China. The South of the Peninsula and Ceylon show distinct affinity with Malaya and to a certain extent with East Africa. Burma, while akin to India, has a strong Malayan bias.

The whole area is divisible into three primary botanical sections: Himalayan, Western and Eastern. These, however, are by no means homologous and are susceptible of further subdivision and they are best considered under the following eight main botanical regions.

The Western Himalayan Region.—This region consists of the western portion of the Himalayas from Chitral to Kumaon and covers a vast depth from north to south, embracing a series of parallel snow-clad ranges. Towards the south the valleys are narrow and tortuous; northwards they are more open and tend to form elevated table-lands which merge into the great Tibetan Plateau. The predominant families are: *Gramineae*, *Leguminosae*, *Cyperaceae*, *Labiatae*, *Ranunculaceae*, *Orchidaceae*, *Cruciferae*, *Rosaceae*, and *Scrophulariaceae*, showing a definite western influence, more especially at the higher levels. In the South sub-tropical trees and shrubs intrude, such as *Boswellia* and *Holoptelia*. The oaks are few and among them is the European Holm Oak (*Quercus Ilex*). Of conifers we find the *Cedrus Deodara*, *Pinus longifolia*, *P. excelsa*, *Abies Pindrow*, *Cupressus torulosa*, *Juniperus macrospora* and in the drier localities *Pinus Gerardiana*.

The Eastern Himalayan Region.—The remainder of the Himalayan range falls into the next region, which is narrower from north to south and has a lower average level. Tropical forms here are more numerous and there is a definite Chinese influence. The dominating families are: *Orchidaceae*, *Gramineae*, *Leguminosae*, *Compositae*, *Cyperaceae*, *Urticaceae* (in the wide sense), *Scrophulariaceae*, *Rosaceae*, *Rubiaceae* and *Euphorbiaceae*. A number of oaks and *Castanopsis* and a large number of *Rhododendrons* characterize this region as also many species of *Primula* and *Meconopsis*. The Deodar hardly occurs at all and few of the conifers of the last region; they are replaced by *Abies Webbiana*, *Picea Morinda*, *Larix Griffithii*, *Tsuga Brunoniana* and two species of *Juniperus*. Tree Magnolias are conspicuous and the tropical influence is emphasized by the presence of numerous species of *Impatiens* and *Orchids*.

The Indus Plain Region.—The Punjab, Sind, Rajputana west of the Aravalli Hills, Cutch and Northern Guzerat make up this region. Over the greater part arid conditions prevail with a very low rainfall and a scanty vegetation which approaches extinction in the Indian Desert. Tree growth is comparatively rare and stunted; the vegetation is mainly herbaceous and is burnt or dried up in the hot season. Thorny species are conspicuously numerous. The dominant families are: *Gramineae*, *Leguminosae*, *Compositae*, *Cyperaceae*, *Scrophulariaceae*, *Labiatae*, *Boraginaceae*, *Malvaceae*, *Euphorbiaceae* and *Convolvulaceae*. Characteristic among the shrubs and undershrubs are *Fagonia arabica*, thorny species of *Capparis* and *Zizyphus* and *Calotropis*. There are two indigenous palms—*Phoenix sylvestris* and *Nanorrhops Ritchieana*—and one bamboo—*Dendrocalamus strictus*.

The Gangetic Plain Region.—Extending from the Aravalli Hills eastwards to the Bay of Bengal, this region comprises all the tract from the Himalayan foothills to the low country of Orissa. There are considerable variations in the vegetation of its different parts, all of which are far more humid than the last region. The dominant families are: *Gramineae*, *Leguminosae*, *Cyperaceae*, *Compositae*, *Scrophulariaceae*, *Malvaceae*, *Acanthaceae*, *Euphorbiaceae*, *Convolvulaceae* and *Labiatae*. The deltas of the Ganges and the Brahmaputra consist of a number of islands which support a dense evergreen forest of trees and shrubs in which the mangroves predominate. A valuable timber tree, the Sal (*Shorea robusta*), is almost confined to this region.

The Malabar Region.—This region occupies a wet zone of mountainous country with a narrow strip of low land between it and the west coast running from Guzerat to Travancore. Its highest peaks attain to a little short of 9,000 feet in elevation. The vegetation generally is very luxuriant and mainly evergreen and

approaches the Malayan type. Dense evergreen forests with thick cane (*Calamus*) brakes and bamboo thickets are characteristic. On the higher hills are found wide expanses of grassy downs dotted with patches of evergreen woods, the remnants of former extensive forests left clinging to the sides of ravines and depressions. In the moderately wet areas below 2,000 feet, the teak—*Tectona grandis*—attains to very large dimensions, growing mixed with a number of other large and valuable timber trees—*Dalbergia*, *Pterocarpus*, *Terminalia*, *Lagerstroemia*—and with *Bambusa arundinacea*. In the wetter forests at moderate elevations *Anonaceae*, *Garcinia*, *Dipterocarpaceae*, *Mesua ferrea*, *Calophyllum*, *Cullenia*, many Rubiaceae trees, shrubs and herbs, *Euphorbiaceae*, *Ficus*, *Artocarpus* and *Zingiberaceae* occur as also a single conifer—*Podocarpus latifolia*—and a number of palms and numerous ferns. In the low-lying swampy localities *Pandanus* and several *Araceae* are noticeable. At higher elevations many Acanthaceae shrubs, particularly of the genus *Strobilanthes*, are prominent and among the trees, species of *Elaeocarpus*, many *Eugenia*s and a tree Composite—*Vernonia monosis*. Epiphytic orchids are fairly numerous and tree ferns appear here and there. Among the grasses of the downs at elevations over 6,000 feet are numerous herbs and undershrubs of *Impatiens*, *Leguminosae*, *Umbelliferae*, *Rubiaceae*, *Compositae*, terrestrial orchids, *Liliaceae*, *Commelinaceae* and patches of the bracken fern.

The Deccan Region.—The whole of the peninsula south of the Ganges valley and east of the Western Ghats is comprised in this region. With the exception of a belt of dry-evergreen, low jungle along part of the east coast, characterised by species of *Capparis*, *Pterospermum*, *Eugenia*, *Ixora*, *Mimusops*, *Diospyros* and *Strychnos*, the vegetation is mainly deciduous and much of it is thorny. *Leguminosae* occupy a conspicuous place; other prominent families, besides the ubiquitous *Gramineae*, are: *Tiliaceae*,

FORT ALI, ON THE KHYBER PASS, WAS ONE OF THE GARRISONS THAT GUARDED THIS IMPORTANT FRONTIER ROAD BETWEEN THE PUNJAB AND AFGHANISTAN

Rhamnaceae, *Rubiaceae*, *Asclepiadaceae*, *Convolvulaceae* and *Euphorbiaceae*, with large areas occupied almost exclusively by one or other of the two common bamboos—*Bambusa arundinacea* and *Dendrocalamus strictus*. On dry rocky hillocks *Givotia rottleriformis*, *Sterculia urens*, *Gyrocarpus Jacquinii*, *Cochlospermum gossypium*, *Cassia Fistula* and *Euphorbia antiquorum* claim attention. Along the coast and in the semi-desert sandy tract in the extreme South the Palmyra palm—*Borassus flabelliformis*—forms dense groves and thickets; similar aggregations of another palm—*Phoenix sylvestris*—occur inland. The true sandalwood—*Santal-*

um album—is found in the south central part.

The chief cultivated plants of British India include rice, wheat, many pulses and grains; castor, *Sesamum* and ground-nut oil-seeds; fruit trees such as the mango, citrus fruits, the coco-nut, Palmyra and Areca-nut palms; apples, pears, peaches, apricots, walnuts in the Himalayan valleys; tea plantations cover large areas in the North as well as in the South Indian mountains and in the latter and in Ceylon are also extensive coffee, rubber, cardamom and pepper gardens. Rubber is also grown in Burma. In several damp localities cinchona is successfully grown. (C. E. C. F.)

FAUNA

Mammals.—The lion (*Felis leo*) was not uncommon within historical times in Hindustan proper and the Punjab. A peculiar variety is preserved in the Gir, or rocky hill-desert and forest of Kathiawar, often described incorrectly as maneless.

The tiger (*F. tigris*), is found in every part of the country, from the slopes of the Himalayas to the Sundarbans swamps. The average length of a tiger from nose to tip of tail is 9 ft. to 10 ft. for tigers, and 8 ft. to 9 ft. for tigresses, but a tiger of 12 ft. 4 in. has been shot. The advance of cultivation, even more than the incessant attacks of sportsmen, has reduced numbers but extermination is very unlikely. The malarious *tardai* fringing the Himalayas, the uninhabitable swamps of the Gangetic delta, and the wide jungles of the central plateau are at present the chief home of the tiger. His favourite food appears to be deer, antelope and wild hog. When these abound he will disregard domestic cattle. Indeed, the natives are disposed to consider him as in some sort their protector, as he saves their crops from destruction by the wild animals on which he feeds. But he may develop a taste for human blood and the confirmed man-eater, generally an old beast disabled from overtaking his usual prey, seems to accumulate victims in sheer cruelty rather than for food. The favourite mode of shooting the tiger is from the back of elephants, or from elevated platforms (*machans*) of boughs in the jungle.

The leopard or panther (*F. pardus*) is far more common than the tiger in all parts of India, and at least equally destructive to life and property. The greatest length of the leopard is about 7 ft. 6 in. A black variety, as beautiful as it is rare, is sometimes found in the extreme south of the peninsula, and also in Java.

The cheetah or hunting leopard (*Cynaelurus jubatus*), found only on the Deccan, is trained for hunting the antelope. The cheetah's limbs are long, its hair rough, and its claws blunt and only partially retractile. Other Indian cats are the ounce or snow leopard (*F. uncia*), the clouded leopard (*F. nebulosa*), the marbled cat (*F. marmorata*), the jungle cat (*F. chaus*), and the viverrine cat (*F. viverrina*).

Wolves (*Canis lupus*) abound in open country preying on sheep, but are said to run down or ambush antelopes and hares. The Indian wolf has a dingy reddish-white fur, some of the hairs being tipped with black. By some naturalists it is regarded as a distinct species, under the name of *Canis pallipes*. Three distinct varieties, the white, the red and the black wolf, are found in the Tibetan Himalayas. The Indian fox (*Vulpes bengalensis*) is comparatively rare, but the jackal (*C. aureus*) abounds.

The wild dog, or dhole (*Cyon*), is found in all the wilder jungles of India. Its characteristic is that it hunts in packs, sometimes containing thirty dogs, and does not give tongue. A peculiar variety of wild dog exists in the Karen hills of Burma, black and white, as hairy as a Skye terrier, and as large as a medium-size spaniel. Among other dogs of India are the pariah, which is merely a mongrel, run wild and half starved; the poligar dog, an immense creature peculiar to the south; the greyhound, used for coursing; and the mastiff of Tibet and Bhutan. The striped hyaena (*Hyaena striata*) is common, being found wherever the wolf is absent. Like the wolf, it is very destructive.

Of bears, the common black or sloth bear (*Melursus ursinus*) is common throughout India wherever rocky hills and forests occur. It is distinguished by a white horse-shoe mark on its breast. Its food consists of ants, honey and fruit. When disturbed it will attack man, and it is a dangerous antagonist, for it always strikes at the face. The Himalayan or Tibetan sun bear (*Ursus tor-*

quatus) is found along the north, from the Punjab to Assam. During the summer it remains high up in the mountains, near the limit of snow, but in the winter it descends to 5,000 ft. and even lower. Its congener, the Malayan sun bear (*U. malayanus*), is found in Lower Burma.

The elephant (*Elephas indicus*) is now, at any rate, an inhabitant, not of the plains, but of the hills; and even on the hills it is usually found among the higher ridges and plateaus, and not in the valleys. From the peninsula of India the elephant has been gradually exterminated, being only found now in the primeval forests of Coorg, Mysore and Travancore, and in the tributary states of Orissa. It still exists in places along the *tarāi* or submontane fringe of the Himalayas. The main source of supply is the north-east transition zone from Assam to Burma. Two varieties are there distinguished, the *gunda* or tusker, and the *makna* or *kine*, which has no tusks. The maximum height is probably 12 ft. The elephant must be hunted on foot. A special law, under the title of "The Elephants Preservation Act" (No. VI. of 1879), regulates the licensing of hunting.

Of the rhinoceros, three distinct varieties are enumerated, two with a single and one with a double horn. The most familiar is the *Rhinoceros unicornis*, commonly found in the Brahmaputra valley. It has but one horn, and is covered with massive folds of naked skin. It sometimes attains a height of 6 ft.; its long horn is much prized by natives for medicinal purposes. The Javan rhinoceros (*R. sondaicus*) is found in the Sundarbans and also in Burma. It also has but one horn, and mainly differs from the foregoing in being smaller, and having less prominent "shields." The Sumatran rhinoceros (*R. sumatrensis*) is found from Chittagong southwards through Burma. It has two horns and a bristly coat.

The wild hog (*Sus cristatus*) is well known. It frequents cultivated situations, and is the most mischievous enemy of the villager. A rare animal, called the pigmy hog (*S. salvanius*), exists in the *tarāi* of Nepal and Sikkim, and has been shot in Assam. Its height is only 10 in., and its weight does not exceed 12 lb.

The wild ass (*Equus hemionus*) is confined to the sandy deserts of Sind and Cutch, where it is almost unapproachable.

Many wild species of the sheep and goat tribe are to be found in the Himalayan ranges. The *Ovis ammon* and *O. poli* are Tibetan rather than Indian species. The *urial* and the *shapu* are kindred species of wild sheep (*Ovis vignei*), found respectively in Ladakh and the Suleiman range. The former comes down to 2,000 ft. above the sea, the latter is never seen at altitudes lower than 12,000 ft. The *barhal*, or blue wild sheep (*O. nahura*), and the *markhor* and *tahr* (both wild goats), also inhabit the Himalayas. A variety of the ibex is also found there, as well as in the highest ranges of southern India. The *sarau* (*Nemorhaedus bubalinus*), allied to the chamois, inhabits the mountains of the north.

The antelope tribe is represented by comparatively few species, as compared with the great number peculiar to Africa. The antelope proper (*Antelope*), the "black buck" of sportsmen, is very generally distributed. Its special habitat is salt plains, as on the coast-line of Gujarat and Orissa, where herds of fifty does may be seen, accompanied by a single buck. The doe is of a light fawn colour and has no horns. The colour of the buck is a deep brown-black above, sharply marked off from the white of the belly. His spiral horns, twisted for three or four turns like a corkscrew, often reach the length of 30 in. The flesh is dry and unsavoury, but is permitted meat for Hindus, even of the Brahman caste. The *nilgai* or blue cow (*Boselaphus tragocamelus*) is also widely distributed, but specially abounds in Hindustan Proper and Gujarat. As with the antelope, the male alone has the dark-blue colour. The *nilgai* is held peculiarly sacred by Hindus, from its fancied kinship to the cow. The four-horned antelope (*Tetracerus quadricornis*) and the gazelle (*Gazella bennetti*), the chinkara or "ravine deer" of sportsmen, are also found in India.

The *sambhar* or *jarau* (*Cervus unicolor*) is found on the forest-clad hills in all parts. It is of a deep-brown colour, with hair on its neck almost like a mane; and it stands nearly 5 ft. high, with spreading antlers nearly 3 ft. in length. Next in size is the swamp deer or *bara-singha*, signifying "twelve points" (*C. duvauceli*), which is common in Lower Bengal and Assam. The *chital* or

spotted deer (*C. axis*) is generally admitted to be the most beautiful inhabitant of the Indian jungles. Other species include the hog deer (*C. porcinus*), the barking deer or muntjac (*Cervulus muntjac*), and the chevrotain or mouse deer (*Tragulus meminna*). The musk deer (*Moschus moschiferus*) is confined to Tibet.

The gaur (*Bos gaurus*), the "bison" of sportsmen, is found in the hill jungles, in the Western Ghats, in Central India, also in Assam, and in Burma. This animal sometimes attains a height of 20 hands (close on 7 ft.), measuring from the hump above the shoulder. Its short curved horns and skull are enormously massive. Its colour is dark chestnut, or coffee-brown. From the difficult nature of its habitat, and from the ferocity with which it charges an enemy, the pursuit of the bison is no less dangerous and no less exciting than that of the tiger or the elephant. Akin to the gaur, though not identical, are the *gayāl*, or *mithun* (*B. frontalis*), confined to the hills of the north-east frontier, where it is domesticated for sacrificial purposes by the aboriginal tribes, and the *tsine* or *banting* (*B. sondaicus*), found in Burma. The wild buffalo (*Bos bubalus*) differs from the tame buffalo only in being larger and more fierce. The finest specimens come from Assam and Burma. The horns of the bull are thicker than those of the cow, but the horns of the cow are larger. A head has been known to measure 13 ft. 6 in. in circumference, and 6 ft. 6 in. between the tips. The greatest height is 6 ft. The colour is a slaty black; the hide is immensely thick, with scanty hairs.

The rat and mouse family is only too numerous. The loathsome bandicoot (*Nesocia bandicota*), which sometimes measures 2 ft. in length, including its tail, and weighs 3 lb., burrows under houses, and is very destructive to plants, fruit and even poultry. More interesting is the tree mouse (*Vandeleusia*), about 7 in. long, which makes its nest in palms and bamboos. The field rats (*Mus mettada*) occasionally multiply so exceedingly as to diminish the out-turn of the local harvest.

Birds.—The ornithology of India is not considered so rich in specimens of gorgeous and variegated plumage as that of other tropical regions. The parrot tribe is the most remarkable for beauty. Four vultures are found, including the common scavengers (*Gyps indicus* and *G. bengalensis*). The eagles comprise many species, but none to surpass the golden eagle of Europe. Of falcons, there are the peregrine (*F. peregrinus*), the *shain* (*F. peregrinator*), and the *lagar* (*F. jugger*), which are all trained by the Indians for hawking; of hawks, the *shikara* (*Astur badius*), the goshawk (*A. palumbarius*), and the sparrow-hawk (*Accipiter nisus*). Kingfishers of various kinds and herons are sought for their plumage. The *maina* (*Acridotheres tristis*), a member of the starling family, lives contentedly in a cage, and talks well. Snipe (*Gallinago coelestis*), pigeons, partridges, quail, plover, duck, teal, sheldrake, widgeon—all of many varieties—make up the list of small game. The red jungle fowl (*Gallus ferrugineus*), supposed to be the ancestor of our own poultry, is not good eating; and the same may be said of the peacock (*Pavo cristatus*).

Reptiles.—Serpents swarm in gardens, and intrude into dwellings, especially in the rainy season. The cobra di capello (*Naja tripudians*)—the name given to it by the Portuguese, from the appearance of a hood produced by the expanded skin about the neck—is the most dreaded. The Russelian snake (*Vipera russellii*), about 4 ft. in length, is of a pale yellowish-brown, beautifully variegated with large oval spots of deep brown, with a white edging. Its bite is extremely fatal. All the salt-water snakes in India are poisonous; the fresh-water forms are innocuous.

The other reptiles include two species of crocodile (*C. porosus* and *C. palustris*) and the ghariyal (*Gavialis gangeticus*). These are more ugly than destructive. Scorpions abound.

Fishes.—Fish are eaten as nearly fresh as may be, for the art of curing them is not generally practised, owing to the exigencies of the salt monopoly. At Goalanda, at the junction of the Brahmaputra with the Ganges, and along the Madras coast many establishments exist for salting fish in bond. Among edible Indian fishes, the *Cyprinidae* or carp family and the *Siluridae* or cat-fishes are best represented. From the angler's point of view, by far the finest fish is the *mahseer* (*Barbus*), found in all hill streams, whether in Assam, the Punjab or the South. The *mahseer*

is a species of barbel. One of the richest and most delicious of Indian fishes is the *hilsa* (*Clupea ilisha*).

Insects.—Mosquitoes are innumerable, and moths and ants of the most destructive kind, as well as others equally noxious and disagreeable. Amongst those which are useful are the bee, the silk-worm, and the insect that produces lac. Clouds of locusts occasionally appear, which leave no green thing behind them. There are many beautiful butterflies. (X.)

ETHNOLOGY AND RELIGION

Racial Origins and Types.—With a population of 319 millions (one-fifth of the whole human race) such as India possesses, racial origins are incapable of exact definition. It is generally accepted however that, in remote antiquity, India was occupied by a negroid people of low culture, ethnically related to the aborigines of Ceylon, Sumatra and possibly even Australia. At a still pre-historic stage, it is believed that an inflow of what are loosely called Dravidian races made its way through Baluchistan from Western Asia, and slowly penetrated India to the far south. Another pre-historic movement, more restricted in its scope, was an infiltration of Mongoloid races from the north-east. The fusion of these elements with the indigenes had probably gone far when the long series of invasions from outer Asia through the north-west passes began. From that period successive waves, starting with the Indo-Aryans and ending in historical times with the Moslem invasions, have swept through and got largely absorbed among the older inhabitants. Eight racial types can be traced with some confidence and for them, Risley's names are provisionally retained though it is recognised that progress of research has converted some of them into mere labels. Dravidian and Scythian as racial names are used without relation to linguistic or historical facts.

(1) The aboriginal or pre-Dravidian type, surviving in the short, platyrrhine men of certain scattered primitive tribes of the

RAJPUT PEASANTS AT A FAIR IN JHALRAPATAN, RAJPUTANA

hills and jungles, such as the Santals and Bhils, and farther south, the Paniyan, Kadir, Kurumba, Irula, Kanihar, etc.

(2) The Dravidian type, now extending from Ceylon, all over the Southern peninsula, up to the Gangetic valley.

(3) The Indo-Aryan type, in Kashmir, tailing off into the Punjab and Rajputana.

(4) The Aryo-Dravidian or Hindustani type in the Gangetic valley, the product of the absorption into a mainly Dravidian population, of colonies from the more definitely Indo-Aryan country farther west.

(5) The Scytho-Dravidian type, running east of the Indus, down through Gujerat and the western part of Bombay, and represented chiefly by the Mahrattas.

(6) The Turko-Iranian type, found west of the Indus on the north-west frontier and adjoining districts.

(7) The Mongoloid type, in Burma, Assam and among the foot-hills of the eastern Himalayas, clearly originating in China and Tibet.

(8) The Mongolo-Dravidian type, probably a blend of Dravidian and Mongoloid elements, with a strain of Indo-Aryan blood in the higher groups, of which the Bengalis are unmistakable representatives.

Religions.—The chief Indian religions, with the numbers of their followers according to the census of 1921 are: Hindu (216,734,586), Mohammedan (68,735,233), Buddhist (11,571,268), Sikh (3,238,803), Jain (1,178,596), Christian (4,754,064), Parsee (101,778), and Animist (9,774,611). The oldest of these religions is Animism (*q.v.*), which represents the beginnings of religion in India, and is still professed by the more primitive tribes, such as Santals, Bhils and Gonds. The transition from this crude form of religion to popular Hinduism is comparatively easy. The most obvious characteristics of the ordinary Hindu are that he worships a plurality of gods, looks upon the cow as a sacred animal, regards certain rivers and pools as holy, and accepts the Brahmanical supremacy and the caste system; and when it is a question whether one of the animistic tribes has or has not entered the fold of Hinduism, these seem to be the proper test to apply. On the other hand there are various offshoots from orthodox Hinduism, the distinguishing feature of which, in their earlier history at least, is the obliteration of caste distinctions and the rejection of the Brahmanical hierarchy. It is doubtful if Buddhism, and still more so if Jainism and Sikhism, all of which are commonly recognized as distinct religions, ever differed from Hinduism to a greater extent than did the tenets of the earlier followers of Chaitanya in Bengal or those of the Lingayats in Mysore; and yet these latter two are regarded only as sects of Hinduism. Considerations of their history and past political importance have led to the elevation of Buddhism, Jainism and Sikhism to the rank of independent religions, while the numerous other schismatic bodies are held to be only sects. But there is a marked tendency both on the part of the sects and of the distinct religions to lapse into the parent religion from which they sprang.

The bewildering diversity of religious beliefs collected under the name of Hinduism has no counterpart amongst the Mohammedans, who are limited as to their main tenets by the teaching of a single book, the Koran. The two main sects are the Sunnis and the Shiah. In India the Sunnis greatly preponderate, but they usually share with the Shiah their veneration for Hasan and Husain and strictly observe the Mohurrum.

Muslims.—The Mohammedans of India may be divided into two classes, pure Mohammedans from the Mogul and Pathan conquering races, and Mohammedan converts, who differ very little from the surrounding Hindu population from which they originally sprang. The pure Mohammedans may again be subdivided into four sections: Moguls, or the descendants of the last conquering race, including Persians; Afghans or Pathans, in the Punjab and in the Rohilkhand division of the United Provinces; Saiyads, who claim to be lineally descended from the Prophet; and Sheikhs, which is a name often adopted by converts. The remainder are unspecified. In Bengal the vast majority of the Mohammedans in their devotion to hereditary occupations are scarcely to be distinguished from Hindu castes. In the Punjab, besides the Pathan immigrants from across the frontier, Islam has taken a strong hold of the Jats, Rajputs and Gujars. Bombay possesses three peculiar classes of Mussulmans, each of which is specially devoted to maritime trade—the Memons, chiefly in Sind; the Borahs, mainly in Gujerat; and the Khojahs, of whom half live in the island of Bombay. In southern India are found the two peculiar races of the Moplahs and the Labbays, both of which are seated along the coast and follow a seafaring life. They are descended from the Arab traders who settled there in very early times, and were recruited partly by voluntary adhesions and

partly by forcible conversions during the persecutions of Hyder Ali and Tippoo Sultan. The Moplahs of Malabar are notorious for repeated outbreaks of bloody fanaticism. In proportion to the total population Islam is most strongly represented in the North-West Frontier Province, where it is the religion of 92% of the inhabitants; then follow Kashmir and Sind with about 75% each, Bengal with 54%, the Punjab with 55%, and the United Provinces with 14%. In the great Mohammedan state of Hyderabad the proportion is only 10%.

The Sikh religion is almost entirely confined to the Punjab, its adherents numbering 3,237,449. Buddhism had disappeared from India long before the East India Company gained a foothold in the country, and at the present day there are very few Buddhists in India outside Burma, where they number over 11 millions. More than two-fifths of the Jains in India (1,178,596 in all) are found in Bombay and its states, including Baroda. The Parsees, though influential and wealthy, are a very small community, numbering only 102,000, of whom all but 19,000 are found in Bombay. The remainder are scattered all over India.

Christians.—The Christian community numbers 4,753,937, of whom 4,464,396 are Indians and the remainder Europeans and Anglo-Indians. Of the Indian Christians about two-fifths are Roman Catholics. More than half of the Indian Christians are found in Madras and the adjoining states, a tribute to the labours of St. Francis Xavier and the Protestant missionary Schwarz. The adherents of the Syrian church, known as "Christians of St. Thomas," in Malabar, Travancore and Cochin are the most ancient Christian community in the south. After these come the Roman Catholics, who trace their origin to the teaching of St. Francis Xavier and the Madura Jesuits. The Protestant churches date only from about the beginning of the 19th century, but their progress since that time has been considerable. As is to be expected in the case of a religion with a strong proselytizing agency, the growth of Christianity is far more rapid than that of the general population. Taking Indian Christians alone, their numbers increased from 1,246,288 in 1872 to 4,464,396 in 1921, and the rate of increase was even greater than these figures would show, because they include the Syrian church, whose numbers are practically constant. The classes most receptive of Christianity are those who are outside the Hindu system, or whom Hinduism regards as degraded. Conversions from Islam are relatively scarce.

Caste.—So far as Hinduism is concerned, the intermixing of the racial types described above has left one definite ethnical legacy in Caste; for it is apparently from the differences in civilization and political power resulting from the imposition of successive strata of conquerors over the conquered that the Hindu system of caste arose. The Census report of 1911 defines a caste as "an endogamous group or collection of such groups bearing a common name and having the same traditional occupation, who are so linked together by these and other ties, such as the tradition of a common origin and the possession of the same tutelary deity, and the same social status, ceremonial observances and family priests, that they regard themselves, and are regarded by others, as forming a single homogeneous community." Not only is the caste usually endogamous, but within it there are a number of smaller circles, each of which is also endogamous. Caste has come to be the chief factor in the life of the ordinary Hindu, regulating his acts from the cradle to the grave; and its influence extends to the Mohammedan masses who are descended from the more recent converts to Islam. (See CASTE.)

Languages.—According to the linguistic survey of India, no fewer than 220 distinct languages are recorded as vernacular in the country. These are grouped in linguistic families as follows:—

Austro-Asiatic	
Mon-Khmer (550,000)	10
Munda (3,974,000)	7
Tibeto-Chinese (12,885,000)	145
Dravidian (64,128,000)	14
Karen (1,114,000)	15
Indo-European, Aryan (232,847,000)	25
Smaller families (27,000)	6
Total Vernaculars of India	222

The Mon-Khmer sub-family, which is most numerous in Indo-China, is represented in India by the Talaings of southern Burma and the Khasis of Assam. The Munda languages, belonging to the Austric family of speech, are chiefly confined to Chota Nagpur, their best-known tribe the Santals. Of the Tibeto-Chinese family, the main groups are spoken from Tibet to Burma; while the Siamese-Chinese sub-family is represented by the Shans of Burma. The Dravidian family includes the four literary languages of the south, as well as many dialects spoken by hill tribes in Central India, and also the isolated Brahui in Baluchistan. The Indo-European family embraces the tongues of the great mass of the people of northern India. (ME.)

PEOPLES OF INDIA

The discoveries at Mohenjo-Daro include the skeletal remains of a dolichocephalic (long-headed) people, who, in Sir John Marshall's opinion, "may reasonably be assumed to have belonged to the great long-headed race of Southern Asia and Europe to which the name 'Mediterranean' is commonly applied" (*Times*, Jan. 4, 1928). One skull approximating to the brachycephalic (round-headed) type, which seems to possess the same characteristics as the pronouncedly brachycephalic statues, was found from a fractional burial. These remains are of the Chalcolithic period and subsequent to the abandonment of the latest city (c. 2500 B.C.). Two skulls found buried deep in alluvial deposits near Bombay are perhaps 2,000 years old and are regarded by Sir Arthur Keith as of the small size and narrow shape now prevalent in India. Two of the skulls discovered at Aditanallur in a prehistoric burial site are conspicuously prognathous (with prominent jaws), and others are markedly long-headed, this latter a feature still noticeable in southern India. In early Indian literature mention is made of people having the complexion of a charred stake, flattened features and very short stature, a type quite common in the present population of the continent.

Melanoderms.—The Andamanese (*q.v.*), are typical Negritos and these people can be considered to be a pure race. They have black skins, woolly hair, very broad noses, round heads and everted lips. It is possible that this element may at one time have existed on the continent but it has left no traces in the present population. More widely spread is a stock marked by short stature, longish heads, broad noses, very dark skins and curly, even frizzly, hair and lips inclined to be everted. This class includes in its numbers the jungle tribes of southern India and of Chota Nagpur, the lower castes in western Bengal and to a slight extent the lowest castes in upper India. This element appears to be related to the Veddas of Ceylon, the Sakai of the Malay peninsula and the Australoids. Here and there woolly-haired individuals may be found but they may be merely aberrant forms or due to recent African admixture.

Leucoderms.—An important element, conspicuous in southern, but found in western, India as well, is long headed, with medium to fine noses, shortish, with darkish skin and fine wavy hair. The lips are thin. This element resembles in many respects the Mediterranean stock. The dominant element in the northern, especially the north-western, area is tall, long headed, with fine noses, fair skins (allowing for the effects of exposure to the sun) and in many instances with light-coloured eyes. The lips are thin. It is a type represented among the higher castes of Bengal, and the Nambutiri Brahmans of Malabar, the Nayars, the Coorgs and the Todas also must be regarded as of this stock. In the mountain regions on the west and in Baluchistan is found a round-headed stock, fairly tall, with fine features, wavy hair, ranging from dark brown to fair, and occasional lightish eyes, which seems to be affine to the Alpine stock. A somewhat similar round-headed element can be traced along the west coast but is darker in skin, hair and eyes.

Xanthoderms.—Many groups in central, northern and eastern Bengal have Mongoloid features and the Savaras on the east coast in the Madras presidency have the Mongolian eyefold. While these main elements may be distinguished in the Indian population, miscegenation has taken place in varying intensity under different conditions all over the continent from prehistoric times. Varia-

tions of humidity, temperature, altitude, mode of life, have also had their effect.

The dissociation of language and race is complete in many parts of India so that terms such as Aryan or Dravidian, which have or may have some value when applied separately either to linguistic or to racial groups, have no significance when attached indiscriminately. Such terms have been avoided here.

BIBLIOGRAPHY.—*Cambridge History of India*, ed. E. J. Rapson (vol. i., 1922); Roland B. Dixon, *Racial History of Man* (1923); A. C. Haddon, *The Races of Man* (1924); Sir Arthur Keith, *The Antiquity of Man* (2nd ed., 1925).

Social Organization.—The evidence as to the social system of the early Vedic Aryas is singularly vague. They were settled in the Punjab between the Indus and the Sarasvati, but had also occupied lands on the Jumna and even on the upper Ganges. This area was of very varying fertility. Probably the central Punjab was then, as later, a barren steppe; but the riverain tracts, the Kurukshetra and the sub-Himalayan belt were doubtless fertile, well-wooded and possibly densely forested. We may thus expect to find pastoral types in the steppes and agricultural in the cultivable areas. We have no good reason to assume that the Aryas found these lands unpeopled; on the contrary the pre-Aryans of the north were probably quite as advanced as the Dravidians who seem to have been settled in villages from an early period. Even in the *Rig-veda* we find mention of measured fields, and of ploughlands. The village (*grama*) sometimes contained a fort (*pur*), doubtless a tower, and might be of considerable size. Grain was certainly stored, so the villagers cannot always have been nomadic; but hints are given that the "village"-folk was in places a body of herdsmen, wandering in search of pasture under the guidance of the god Pushān. Of the social economy of the settled villages, we learn little. At its head was the village leader, but he seems to have been the chief of its militia, often connected with the *senāni*, or "leader of the host," which would be quite compatible with the exercise of civil or fiscal functions.

Of village councils we hear nothing, although assemblies (*sabha samiti*) of the people met to advise the king; but in the Epics they disappear.

The village body included such artisans as the *rathakara*, "chariotmaker," carpenter, smith, and others, but they are not described as members of it. Only once do we read of a *gramyavādin*, seemingly a village judge. Indeed we find no term to define a "village-owner" in any way equivalent to the modern usage. On the other hand the king's relation to the soil is equally indefinite. That he was not formally its superior owner is clear, yet he could grant villages or assign his fiscal rights over them to favourites, though such gifts to Brahmans were reproved. And later the idea developed that he was legal owner of the soil, and that his grantees were landlords. Doubtless the feuds alluded to, between nobles and people, arose out of these nebulous relations.

Tribal Organization.—When we turn to the Vedic organization of the tribes the darkness deepens. The *vish* was the people as opposed to the *kshatra*, "nobility," but originally the word doubtless meant "settlement" or merely "dwelling," and the head of it was the *vishpati*, its "lord"; but again the king is *vishpati* as "lord of the people." The *vish* did not, however, include all the *jana*, a term which means "man" and collectively "people" or "tribe." It seems to have denoted the "host" collectively as well as units of it, but whether those units were clans or cantons is not explained, and we have no mention of either tribal chiefs or headmen of cantons. We cannot, however, be very wrong if

we picture the Aryan hosts as composed of tribal rather than territorial levies under their own "kings" (*vishpatis*), obeying the *senani* or *senapati* with village-leaders under them.

Village Community.—The process whereby the Aryan village developed into the modern village community is nowhere described, but it is not difficult to form some idea of it. First of its factors must have been a change in inheritance laws which now gave each son an equal share in the paternal land. This stereotyped the sept or *gotra*. Meaning at first merely a "herd" or "cowstall," this word assumed later a new significance. A change of *gotra* once quite possible became unthinkable and marriage within it was disallowed. The older system had only prohibited it within three or four degrees on either side, and even so permitted a union with the daughter of a paternal uncle, but some instinctive dread of in-breeding seems to have extended the exogamous principle not only to the whole *gotra* necessitating its immutability, but to the descendants of three more kinships, the mother's and the grandparents'. The result was a solidifying, as it were, of the proprietary body which held a village or a number of villages, whether grouped or dispersed. This principle was applied with equal stringency to non-landholding castes of all degrees, though it was often relaxed so as to exclude only one or two kinships beside the paternal *gotra*, and in extreme cases it might be further relaxed by splitting even that *gotra* into two, after a long period of time had reduced the perils of in-breeding to zero. The original *gotra* indeed seems to have been an artificial unit, at least among the Brahmans, whose *gotras*, named after the semi-mythical sages (*rishis*) may well have included their disciples as well as their own issue. Not until the Epic period do we find one of the *Upanishads* enunciating the rule that spiritual succession must descend from father to son, thus closing the *gotra* to new blood. It is, however, important to note here that in the south of India the exogamous instinct still permits cross-cousin marriage.

The village community no doubt has been, and still is, a real commonwealth. But if we ask how it has enforced its collective will, we shall find it rarely evolving a constitution written or unwritten. Sporadically, in the south of India some interesting inscriptions of the 10th century tell us of village committees, under royal control, on which the members sat in rotation determined by lot. It is not clear that they were elected. But a low-caste man was eligible if he had undergone expiation.

But elsewhere investigation fails to trace any ordered forms of village rule. The convention of the village owners, often called its *panchāyat* or "council of five," includes in fact all its members, but it is singularly like the old Polish diet. It has no lawful means, but merely public opinion or collective force, of enforcing its decisions, its customs or its reforms. Its headmen rarely possess definite authority. The wonder is that it has achieved so much. It has enabled provinces devastated by war to reconstruct their rural economy. It has helped vaster areas, ruined by repeated famines, to recover their prosperity. It has re-peopled regions left desolate by massacres like those of Timūr. But it has failed to set up any working system of self-government on which could be grafted a legal structure. No doubt the Indian village varies in the types of its tenures. In the north its lands may be held on the precise shares heritable by descent, the tenure favoured by the Rājputs. Or it may be that in the fragmentation of the holdings ancestral right is no longer the measure of actual occupation which has been allowed to individual co-parceners according to their energy and enterprise; so that the industrious having brought much of the common waste under the plough have bequeathed to their descendants, on its final partition, an indefeasible right to the lion's share of what is left of it. Recently much has been done to consolidate holdings, by enforced mutual exchange of scattered ones, but only under State action. In the south of India a more individualistic system was observed to exist by the earliest British administrators. There they found the village not strictly regarded by its former rulers as collectively responsible for the payment of its land-tax, and consisting of individual holdings. The village community therefore was held to be less often existent and the *ryot-wari*, or system whereby each holder paid his own land tax to the government was favoured.

TAMIL GIRLS OF SOUTHERN INDIA

Social Economics.—The repercussions of these economic phases in Indian society have been marked. The refusal to endure primogeniture has fragmented wealth too rapidly and above all impoverished the smaller gentry who have been compelled to adopt widow re-marriage as an economy. The denial of all testamentary power to the father has weakened social discipline. Hindu law and custom often almost entail property on all the sons alike, abolishing incentives to effort in the cadets. Indian society must not be regarded as aristocratic but as an infinite series of democratic strata lying one above another. Within the *gotra*, now the *got* or whatever its modern synonym may be, all men are equal. But the dictum at once calls for qualification. Within the *got* individuals shall not excel, but groups may, and so where a *got* holds a big cluster of villages and hamlets, one or two bigger, older or more prosperous than the rest, will set up a claim to be superior to the rest. This superiority will be manifested by a denial of brides to a hitherto equal clan, extra extravagance at births, weddings, funerals and so on. But the cost of placing daughters hypergamously or even isogamously being prohibitive, they will be made away with or so neglected that their chances of life are far below those of boys. (See INFANTICIDE.) Hence a loss of almost a moiety of the best-bred strata in the finest *gots*, an unparalleled sacrifice on the altar of snobbery. But the repercussions spread further. The *gotra* must always have been an unprogressive body, its pace being that of its slowest members, and the *got* has inherited its retardation, and it has rarely if ever created a council of canton or tribe. It has had a keen spirit of tribal self-esteem. It has done nothing to advance self-administration in the village or over it.

So far what has been said applies peculiarly to the Hindu castes, including the Sikhs and Mohammedanized tribes which hold the plains of northern India. In the south, caste is tenser, but there is less apparent tendency to subdivide socially. On the other hand two great factions—the right-hand, which is headed by the Brahmans, and includes curiously the Pariahs; and the left-hand, headed by the Panchālars, the “five-castes,” workers in stone, metal, etc., and including the Pullars or Pullans—have been formed.

How the feud between these factions originated is unknown. The causes of collision were trivial and apparently for the most part of a purely sumptuary character. The Pullans are agricultural serfs, little, if at all, above the Pariahs. Offspring of a Brahman woman by a Shūdra, Devendra, they say created the work for the Tamil peasantry, which hints at a pre-Tamil origin. A stocky, sturdy black man eating meat (but not beef, and so superior to the Pariahs) the Pullan specializes in the cultivation of wet rice-land, but is excelled by his woman-folk. Some old sumptuary law forbade a Pullan woman to be clothed above the waist, and when Christian converts broke this rule disturbances ensued. Divided into numerous endogamous and innumerable exogamous groups, they trace descent through females and bury their dead. Yet they adopted some Hindu gods and even claim descent from Indra. In a faction fight they form the vanguard as do the Pariahs on the other side. Yet, low in the caste as they are, the Pullan evince a considerable power of self-organization. They have caste-councils which punish theft and adultery and discipline is enforced by flogging (of both sexes) or expulsion from the caste.

In northern India it may be said that caste self-government is confined to the artisan castes, with occasional guild committees among the traders. But no general assemblies ever seem to have existed. The traders settle commercial disputes in townships and their associations may also decide matrimonial conundrums, but the latter form the main if not the sole matter which interests the artisan *panchāyats* or juries. These are presided over by elders, usually hereditary, and sometimes have an appellate system. Owing to the dispersion of such castes in the village, the jurisdictional area may be large and it is often co-terminous with an old fiscal area.

A Summing Up.—To sum up, the social organization of India, a continent inhabited by one-sixth of the world's population, presents a wide range of complexity from the simple tribe, an

endogamous group with its exogamous kinship clans, or from the local group, be it village or simple hunting group, with local exogamy, divided into family groups, the *débris* or the rudiments of a clan system, to an organized polity wherein the castes are ranged in order of purity (see CASTE) which is determined by factors deep in the history of the people, some economic, others racial, others purely political. The village (see above) is a microcosm, a replica of the greater organization above, often almost self-contained, always essential. Clearly, there was in Ancient India an advanced urban organization the influence of which upon the social history, upon the development of caste, upon the economic and industrial life of India has not as yet been explored. The family, be it joint or divided—for the practice varies and is conditioned by general social and historical facts—is ultimately in India, as elsewhere, the primal unit in the social organization within which, as the first instrument of cultural tradition, are built up the dispositions which, universalized within the society, become its institutions. Kinship—whether matrilineal, as in Malabar, or, as more generally, patrilineal—is with the *got* or clan system reckoned unilaterally, but with the system of cousin marriage, still, as in the early days, typical of southern India, from the highest to the lowest groups, the true bilaterality of the family appears. In this vast area, with its long history and numerous ethnic contacts, marriage rites have been developed to great variety. Every form of social experiment seems to have been tried. The caste system exhibits even now, with a vigorous endogamy strong with religious and social sanctions, the principle of separatism, of emphasis on the differences between groups, and it finds scope for perennial application. (See CASTE; also HYPERGAMY, POLYGAMY, LEVIRATE, SORORATE, COUSIN MARRIAGE, FAMILY, CLAN, TRIBE.)

RELIGION

The religion is not based on anything exclusively Indian but on old world-wide beliefs and universal thought. Its tenets are often pushed to their extreme logical consequences. It is well-nigh as fissiparous as caste, and while it has often in periods of burning zeal for reform caused the lineaments of caste to fade, it has never erased them, and as denominational enthusiasm wanes, the old caste outlines re-appear, generally with new lines enriching the old pattern.

Vedic Religion.—The principal religion of India is, indeed, not so much a religion as a social system tolerating several creeds, pantheism, polytheism, monotheism and atheism, yet intolerant of foreign monotheists and of its fellow-Indians who have rebelled against the caste system. Hinduism (*q.v.*) has absorbed much and rejected little. It has been a great proselytizing system yet it has had few missionaries. It has accepted something from its opponents, but kept them at arm's length. Its strength lies in its eclecticism and in its insistence on the divinity of its own sacred caste, the Brahmans. It was preceded by primitive beliefs which have been called Animism (*q.v.*). It has developed by taking up those beliefs into its articles, speculating freely in its own way, learning much and unlearning nothing. It has undergone never-ceasing changes and is still unchanged.

Of the earliest pre-Aryan faiths of India, all that can be said is that the Vedic sacrifice was sympathetic magic that was directed to secure the benefits of sunshine and rain in due season. It is not safe to attribute all magical practice to aboriginal Dravidian or non-Aryan sources. The faith of the *Vedas* was untouched by Zoroaster's monotheism, yet in them we may discern at first a struggle towards it and then in the *Atharva-Veda* a re-action towards magic, but we have no evidence that the *Atharva-Veda* owes anything to the indigenous magicians of India. It was indeed rather a revival of Iranian practice. But the admission to canonical rank of the *Atharva-Veda* was none the less of cardinal importance in Indian religious history. It raised the good magician at least to priestly status, and if it denied that status to the evil-working sorcerer it tacitly confessed his power. The *Vedas* en bloc were thus made to appeal to the most primitive instincts and the task of the Brahman simplified. He had not to convert, but merely to assimilate.

In the beliefs of the most backward tribes of India, observers have detected Animism, definable concisely as a worship of spirits including impersonal forces. But it is doubtful if Indian Animism ever had any real conception of an impersonal force. It lacked quite completely a vivid idea of personality. The Santāl who still believes that if he takes a false oath on a piece of tiger skin he will be devoured by a tiger, does not seem to attribute any impersonal power to the relic, but to regard it as a convenient substitute for the live tiger which will eat him if he calls upon him to do so in his oath, and then commits perjury. So inchoate is the concept of personality that his primitive mind fails to draw much distinction between inanimate things and living beings. It is equally incapable of realizing death. Accustomed to obey his living village chiefs, he continues to placate them when dead, but worships neither their ashes nor their memorial stones, nor their spirits. The latter are not deified or even ranked as specially endowed *bongas*, the so-called spirits who in human shape marry Santāl men and maidens, cause disease and mischance when so bidden by witches and display gratitude in tangible form by material acts. The Santāls seem to have no words of their own for ghosts or spirits and their native god is Marang Buru, the "great mountain" whose personality can only be described by using a borrowed term, *deo*, the Sanskrit *deva*, and whose main function appears to be the instruction of maidens in witchcraft. But the Santāls cannot be safely regarded as typical pre-Aryans. They dwell in the eastern outskirts of the Chota Nagpur plateau and are hunters in the forest, not assiduous cultivators. In more favoured localities the Dravidians may have attained a much higher civilization. Still less can we be certain that the conceptions of impersonal forces, of the soul and of a future life were unknown to them and kindred tribes before the Aryan conquests.

Cosmogony.—The *Vedas* however display much loftier conceptions. The cosmogony of the *Rig-Veda* fluctuates between two theories, one regarding the universe as the work of a great architect, the other as the result of natural generation. In the first Indra measured out the six regions, made the expanse of earth and the dome of heaven. He and other gods built a cosmic house of timber, framed on posts but rafterless, and why the sky does not fall is a marvel. Savitri made fast the earth with hands, Vishnu fixed it with pegs and Brihaspati supports its ends. In a frame Indra fixed the air and the morning light enters by the portals of the East. But the generation theory is more complex. Dawn, Ushas, born of Night generates the Sun and morning sacrifice. But parentage is more easily assigned to place than it is to time, so Heaven and Earth, containing all, are universal parents. Dyaus, the sky, is father, the Dawn is his daughter. Generically again, he who is the chief, the most prominent of a group, is their parent. Vāyu, the wind, fathers the storm-gods, Rūdra the Maruts (*q.v.*) or Rudras, Soma all plants, and Sarasvati all rivers. But abstractions are already used figuratively so that the gods are "sons" of immortality and of skill: Agni is son of night, Pūsan of freedom, and Indra of truth. This concept recalls the Semitic idiom. On the other hand in the latest canto the world is primitively imaged as a giant from whose members sprang the universe, Indra and Agni from his mouth which also became the Brahmana, from his arms the Rājanya, "warrior," and from his thighs the Vaishya, "commonalty." His head became the sky, his navel the air and from his feet (which also produced the Shūdra) the earth. Moreover the gods are also moral, all are true and "not deceitful," friendly to honesty and righteousness. In this aspect Varuna (*q.v.*) is foremost. The Vedic gods however lack individ-

uality and clearness of outline. Already in the *Rig-Veda* they are said to be 33 in number, a figure constantly increased. And these gods are graded, classed as celestial, those who dwell above the firmament, aerial and terrestrial.

Functions of Deities.—But when we enquire into each god's special functions we find a singular vagueness, a puzzling overlapping of jurisdictions. It is as if the Vedic Aryans had been formed of a confederacy of tribes, each affecting a god of its own, not differing much one from another, often bearing the same names with function adapted now to pastoral, now to cultivating clans, but generally war-like; and as if these gods had been transferable from tribe to tribe as treaties united their followers. Most of the gods have at least some solar attributes. None has a monopoly. If Varuna upholds physical and moral order, so does Mitra. If Varuna is invoked as universal king (*samrāj*) so are Mitra, Indra and even Agni, as though aspirants to the supreme monarchy over the Aryan hosts grasped and lost political power. Though the Vedic gods remain interdependent, Varuna and Surya subordinate to Indra; Indra, Mitra, Varuna and Rudra to Savitri, and Varuna with the Asvins to Vishnu, every god is praised in turn, even the exalted Varuna being mostly invoked in conjunction with at least one colleague while verses to pairs, triads and groups are frequent. The Vedic pantheon resembles the Aryan polity in that it never arrived at an uncontested monarchy. But the *Rig-Veda* closes with some notable hymns which treat the origin of the world as a philosophical problem, and the sun, as a golden embryo, is given the new name of Prajāpati (hitherto a mere epithet of Savitri) "lord of creatures." Foreshadowing or reflecting some monotheistic innovation, Prajāpati is the All, soon to become the anthropomorphic personification of the desire (*kāma*) which is the first seed. Such in outline is the story of the *Rig-Veda's* development, but it does not exhaust all its slowly achieved conceptions. We must at least add to them the toothless Pūsan, the "prosperer," an indistinct individuality, hardly yet anthropomorphic, who watches over paths and guides the dead on the last road. Naturally such a concept is capable of almost infinite expansion, and Pūsan was later to become a sun-god and Āditya "the preserver of all things," and then to fade into oblivion. The Ādityas, sons of Aditi, a group of some six or more gods whose names are variously given, included not only Mitra and Varuna (Indra was added later) but such minor deities as Aryaman, Bhaga, Dakṣa and Amsu; later they too will be sun-gods and include Vishnu. Aditi denoted bondlessness and may be regarded as the only abstraction personified as a goddess in the *Vedas*. Aditi is the great mistress of the devout, but motherhood is her essential trait. Her epithet is *pastyā*, "housewife." She cannot, however, be safely regarded as "Mother of the Gods" in the *Rig-Veda*, her recognition as such not appearing till the Epic period. Her lesser sons are as indistinct as herself, Bhaga besought to be Bhagavān, "bountiful," and Amsha also connoting "bounty," Aryaman, "comrade" and Dakṣa "dexterity," yet the first must be of great antiquity, *bogū* being "god" in old Slavonic, while Aryaman is Avestan. In Vedic worship goddesses are fairly numerous but quite subordinate even when wives of the high gods like Indrāni. They bear simple names, Ushas (*q.v.*), Night, Earth, Speech, Pārendi or Puramdhi, a goddess of plenty like Dhishana, Ila or Ida "abundance" of milk, later "cow"—Brihaddiva, associated with her, Urvasi, beside Rākā (? giver), soon to personify the full moon. Sinivali, broad-hipped, fair, a mistress of the family, invoked for offspring, later to be called Vishnu's spouse, and, like Kūhū, the new moon; Prishni, "speckled" and Saranyu "swift," indicating recent origins. Not until we come to the *Brahmanas* (*q.v.*) do the wives of the gods have a place in the cult assigned to them apart from their husbands. Lower deities like the *Apsaras* and Gandharvas (*q.v.*), deified priests and heroes like Manu (*q.v.*) animals especially horses, kine (the cow is not to be slain) birds such as Garuda, inanimate objects from rivers and hills down to weapons and tools, but not the phallus, abound. Opposed to the benevolent deities is a host of demons, *asuras* ("gods" in the *Rig-Veda* like the Avestan *ahura*), and *dasus*, possessed of occult power, the term *dasu* being at first applied to the dark aborigines, then to demons of the air, and

finally to slaves; on the other hand *vritras* were at first demons and later human foes; *rakshasas* and others.

In the *Rig-Veda* we find belief in a future life, delectable for those who have done penance, for heroes and generous donors of sacrificial gifts. In the earliest hymns burial of the dead is alluded to but cremation was more in favour, doubtless because the soul ascended to Heaven with the smoke. The *Vedas* contain no hint of a belief in metempsychosis but it appears in a *Brahmana*. Yama (*q.v.*) is essentially the king of the dead, but he is hardly their judge, as they pass between two fires, which burn the wicked and let the good go by. Nor does Yama reign alone.

Modern Religion.—We come now to the doctrines which have led to modern Hinduism. One of the principal of these is that of the transmigration of souls, but we cannot fix the date of its appearance in India even approximately. The *Vedas* contain no trace of it, and the *Brahmanas* only indicate the lines of thought whence it arose. Yet in the *Upanishads* and all later Hindu sacred writings it is accepted, and has influenced nearly all Hindu thought. Through the spread of Buddhism it has become widely promulgated amongst the whole of central, eastern and southern Asia, and Jainism assisted this process, though *karma*, "actions," meant something quite different from its meaning in Hinduism wherein a man's actions in one life determine his position in the next. The doctrines were in their inception atheistical and fixed a man's fate for him by his *karmas* in his lives which were never ending; hence arose a passionate desire to find release from the bonds of sense.

Yet, stranger still, the old Vedic ritual was not abandoned and the *Sutras* which were now written were intended to aid the student, being classified indices of its increasing perplexities, more or less unintelligible by themselves and requiring a commentary to explain them. They reflect ritualism and polytheism which are retained without misgivings as to their contradictions by the *karma* theory.

The Epic Poems.—The *Epics* were composed as popular poems in the 6th–4th centuries B.C., changed into sectarian poems by Vaishnava priests in the 2nd century, and in the 1st and 2nd centuries A.D. enlarged, especially the *Mahabharata*, by Vaishnava theism, into an encyclopaedia. The *Mahabharata* was increased from 2,800 to 100,000 verses, but no one has yet undertaken to sift the original from the added matter and there is considerable disagreement amongst scholars as to the dates above given.

The *Ramayana*, whose author was a man of low caste, is easier to dissect. It contains innumerable superstitions and the doctrines of transmigration and *karma* are not yet full-grown. But the *Mahabharata* is even more primitive. In it everyone eats beef. Brahmins often become warriors. The heroine, Draupadi, is polyandrous. On such documents we can as yet found no final theory as to the origin of the cult of Krishna, who may be identical with Vasudeva, while others hold that he was distinct. Rama was almost certainly a man.

The Upanishads.—In the next great batch of religious writing, the *Upanishads*, we have a less corrupted source. The term means secret doctrine and though the root of every idea in them may be found in the *Brahmanas* it is most probable that they were put together by Kshatriyas. Yet they are assigned to Brahmanical schools and some like the *Chhandogya Upanishad* bear the very names of their *Brahmanas*. The essential teaching of the *Upanishads* is that knowledge gives release. Dating from about 500 B.C. they took form in the lands of the Ganges and the Jumna, and they are followed by versified condensations of little later date. But these introduce Vishnu and Shiva as symbols of Brahma. Isha or Ishvara appears as the Supreme in the *Isha Upanishad*, while in the *Svetashvatara* Shiva is introduced under his older title of Rudra and, for the first time in Hindu literature, *bhakti* or devotional feeling, is spoken of as due to him. In these treatises also first occurs the term Vedanta as a name of the Upanishad philosophy.

Hence by the middle of the 6th century, we find a network of Hindu schools, already in full working order, and represented by the prose *Upanishads* the *Karma Mimamsa*, etc.

Probably in the 4th or 3rd century B.C. appear the Samkhya

and Yoga (*q.v.*) systems. The former admitted Sudras, the latter outcasts as well. The one derived from the *Upanishads* in the main, the latter ultimately from popular magic and hypnotism. The Lokayata or materialistic school was probably also in existence.

Buddhism and Jainism.—But to these must be added Jainism and Buddhism (*qq.v.*) both founded by Kshatriyas, rival faiths of Hinduism. Of Jainism, the older, we have less information. As to Buddhism we have much more, but the one great fact to be stressed here is its pessimism. To the Buddhist, Nirvana meant release by extinction. But this doctrine is not consistently taught and under Asoka's influence we find each great *stupa* or *tope* erected over relics of the Buddha or of a noted preacher a splendid work of art while there is no mention of transmigration, *karma* or nirvana, in all his edicts. They preach ethics such as respect for animal life, proper treatment of slaves and generosity to religious teachers, ignoring all metaphysical teaching—as if it were something too deep or too unimportant for the laity. On such a basis no enduring Buddhist church could be founded and with Asoka's death the great hope for Buddhism dies though it survived for centuries as one of many sects.

Theistic Movements.—The great movement towards theism may be said to have begun about 200 B.C. In the conditions which then prevailed it could hardly have had a more unpromising outlook, and to add to its misfortunes its earliest writings have perished. *Upanishads* continued to be written but its principal manual has disappeared, only the sectarian writings such as the *Samnyasa*, *Yoga*, and *Shiva Upanishads* surviving. It seems indeed to have been an epoch when works which struck at particularism were deliberately destroyed. The original version of the laws of *Manu*, the *Dharmasutra*, was replaced by the *Dharmashastra* in verse. Probably some early versions of the Sankya and Yoga systems also existed, but both have disappeared as have the fundamental texts of the *Vaisheshika*, *Nyaya* and *Charvaka*. The Vaishnavas took over the great epics, and changed their character.

The Bhagavadgita.—Among the twice-born we must recognize two great divisions, the orthodox faithful to the Vedic pantheon and ritual, and the sectarians exalting one god to the neglect of the rest, and in his cult using a ritual and liturgy of non-Vedic origin chiefly by temple and image. The sectarian position was greatly strengthened by the *Bhagavadgita*, the earliest and greatest of the didactic Epics. Its date is disputed. In its present form it cannot be earlier than the 1st or 2nd century A.D., but its original may go back to the 4th century B.C. Suddenly in the added matter of the great epics we find the doctrine of divine incarnation. It is useless to ask whence it came or to point to gods in the *Brahmanas* taking temporarily the forms of animals, fish or dwarf. The Vaishnavas go much further. They identify Vishnu with the Brahman-Atman of the *Upanishads*, and with Krishna to whom is given the title of Bhagavan whence the name of the poem, "The Lord's Song." Vishnu's selection is inexplicable. He was one of the great trio but Brahma was the more likely to be chosen as chief of the gods, as the Supreme. Krishna, man, a partial incarnation of Vishnu in the second stage of the Epic, is promoted as a full incarnation of Vishnu-Brahman. The change is not merely revolutionary but unexplained. The explanation must have been set forth in one of the lost works. The theology of the poem is thus a theism, but still imperfect. The Song is coloured, as it were, with some pantheistic passages.

The *Samkhya*, *Yoga* and *Upanishads* are all dragged in without any attempt to reconcile their differences. It recognizes no animal sacrifice but it tightens up the bonds of caste and establishes the regular worship of ancestors. If the *Dharmashastras* as we have them are those to which it refers the ideal is laid down that every man ought to pass through the four *asramas*, and that not even a virgin widow may re-marry. Scholars who hold that the Song was contaminated by the pantheism of the *Upanishads* in the 2nd century A.D. have much on their side. But how did it in the 2nd century B.C. appear as a purely theistic tract glorifying Krishna? It began as a sectarian thesis, it has become the very cream of orthodoxy.

This by no means exhausts the Vaishnava material in the didac-

tic Epic. It was followed by a flood of writings, notably by the Narayaniya section of the *Mokshadharma* which seems to present a later period in the history of Vaishnavism. In it to the Bhagavata are added the Sattvata and the Pancharatra, the latter a term whose name is not yet explicable and the doctrine of Vyūha or expansion according to which Vishnu exists in four forms, denoting the steps of his ascent to Brahma. It is very difficult to

see what the idea behind this scheme is. The second is Samkarshana, "withdrawn," because Vishnu, identified with primeval matter, was drawn from his mother's womb and placed in Rohini. But Vasudeva is Krishna, Balarama or Samkarshana, Krishna's brother, Pradyumna his son, and Aniruddha one of his grandsons. The *Narayaniya* has 10 incarnations of Vishnu, whereas the *Anugita* only mentions six, adding four to the original two but otherwise making no advance whatsoever. The *Narayaniya* also has a tale of Narada the saint taking a long journey to the north where he came to the White Island in the Sea of Milk wherein white men worshipped Narayana, i.e., Vishnu. Here we have seemingly allusions to Christianity. But as yet there is nothing to suggest any worship of the child Krishna or any association of Krishna with the Gopis, "cowherdresses." The story of his rescue from the wrath of Kamsa is still untold and Radha is not mentioned.

In the didactic Epic, Shiva follows Vishnu, but at a long interval. His new theology is clearly in its inception an imitation. Pasupata, as it is called, is scarcely to be distinguished from Pancharatra. The term is formed from Pasu pati, "lord of flocks," once an epithet of Rudra. Shiv-worshippers to-day revere the phallus (e.g., the Lingayats, q.v.), but though it appears on pre-Christian monuments no mention of it occurs in literature before this period.

Buddhism.—Buddhism was developing similar traits. This can be stated with confidence if we regard the literature which has been preserved. The Mahāyāna is the acute Hinduizing of Buddhism, and in it Buddha is conceived of as the Supreme, boundless in power and wisdom and surrounded by Bodhisattvas just attaining Buddha-hood. The text book of this school was the *Lalita Vistara*, originally the Buddha-biography of the Sarvastivadins but taken over and re-written. In it the old Hindu self-torture all re-appears. In his efforts to save men Analokitesvara, "looking down from above," can save from danger.

Jainism.—With Jainism there was a good deal of literary activity between 200 and 500 A.D., but much of it has been lost. The main writers were connected with Pataliputra and the works of one were used by both the Jain sects. They also adapted the Ramayana. All this shows how the sects were inclined to mingle with the Hindus. But what with lost, re-written, etc., books we know too little to be able to say anything with certainty.

Shakta Worship.—About 550 A.D. we see the dawn of the Shaktas though they may have been known earlier. In this system the god is neutral or inactive—apparently because he must be so if he is to remain beyond the sway of the law of Karma—and his spouse the goddess embodies his energy (*shakti*). The oldest goddess of this type is Durga, the virgin goddess of the Vindhyas. Her alliance as Uma with Shiva is later and she is no longer regarded as a virgin. Here we have palpably a fruitful field for new philosophers, sects and almost religions, and we begin to get on to historical ground. Shankara in the first half of the 9th century takes up the teaching in a series of works attributed to him,

FROM THURSTON, "CASTES AND TRIBES OF SOUTHERN INDIA"

A DEVIL DANCER OF SOUTHERN INDIA IN FULL CEREMONIAL COSTUME

but probably not all from his pen. He certainly, however, wrote commentaries or *Vhashyas* on the *Vedanta-Sutras*, the Song and many of the chief *Upanishads*. Shankara distinguishes between the supreme truth and that of experience. Besides the supreme or *para*-Brahman is a lower (*apara*) one, the world-soul and personal god. All our lower knowledge, our personal experience and conception of ourselves as distinct personalities is ignorance rather than knowledge. Liberation comes when a man rises to true knowledge which is finally granted by the grace of God and for which a man may prepare himself by the study of the Veda and the discipline of the Vedanta. Hence when a man became a Sunnyasi of the Advaita Vedanta he gave up all the duties of the ordinary Hindu, laying aside even the sacred thread. Naturally its illusion and doctrine of double truth led its opponents to term it covert Buddhism. By Shankara's day the *Upanishads*, the Song and the *Vedanta-Sutras* were recognized as fundamental for the Vedanta. Later they were called the Triple Canon. Shankara re-regulated its orders, dividing them into 10, whence their name of Dasnamis. He founded Sringeri in Mysore as his chief monastery where he himself was the head, Govardhan in Puri, Sarada (Saraswati as patroness of sciences) in Dwarka, and Joshi at Badrinath. And he was able to do what is rare in Hinduism, viz., reform the Bhagavatas, a Ramaite sect in the south, and the Shaivas of Kashmir. Many other writers followed. The Puranas, whose history is as old as it is obscure, had virtually all come into existence by the end of this period and two of them betray Shakta influence.

The Vaishnavas of the Bhagavata school also accepted the Advaita Vedanta and the five gods, but still more serious was their identification of Shiva with Vishnu in the Skanda *Upanishad*. To-day in the Tamil country the ritual is that of the Pancharatra Samhitas said to be unorthodox as inconsistent with Vedic usage, but we cannot be certain when they were written.

The Samhitas.—The Samhitas mark first the appearance of Shakta principles among the Vaishnavas, indeed the theology of the chief one is a development of the Narayaniya episode with the considerable addition of Shaktism. The basis of their philosophy is the theistic Yoga, but it is manipulated so that it is hardly recognizable. Vishnu and his Shakti are one in the primary creation which is followed by 36,000 secondary ones in which a Samkhyan evolution appears. Their description is that of an attempt to combine most of what has gone before into a single but disconnected system. Even magic is commended. The Sri-Vaishnavas have a sect-mark, two white curving lines with a vertical red one between them, the red representing Vishnu's Shakti. The Samhitas ordain that this symbol shall also be branded on the body. The cult is open to all four castes but not to outcasts. But besides the Sri-Vaishnava several other sects arose, notably the Narsimha (Narsingh) sect which worships the man-lion incarnation of Vishnu, especially in the south and had two *Upanishads* of its own, and these were so popular that they were imitated in other sects. The Shaivas had a bewildering number of sects and schools such as the Kapalikas or skull-men, perpetrating human sacrifice and full of Shakta ideas.

Durga Worship.—The sect of Durga now reorganized with a new theology, a more varied cult, and a fresh literature, appears as the Shakta sect. Its writings still await scholarly investigation but many of them were in existence by 600 A.D. Its system is fundamentally an unlimited array of magic rites drawn from the practices of the most ignorant classes; and it has been credited with ritual usually ascribed to secret sects. It was divided into the left-handed or those who pushed such usages to an extreme, and the right-handed as reformed possibly by Shankara.

Bhakti.—Between 900 and 1350 A.D. we have a new movement in Hindu literature—that of Bhakti. The earlier singers of the Tamil country, the Alvars, in their lyrics introduced great changes in the Sri-Vaishnava temples and paved the way for Ramanuja whose influence re-acted on all the sects.

So, too, the chauntries of the Shaiva gave their cults a great uplift and made possible the creation of the Tamil Shaiva Siddhanta. The two great books are the *Sri-Bhashya* of Ramanuja and the *Bhagavata Paurana*, whence sprang two streams of Bhakti, the one meditative, the other explosively emotional. While the

Shankhya and Yoga schools stood still all the others continued their literary activity in which Bhaskaracharya, author of the *Bhaskara-Chashya*, attacks Shankara and in turn is assailed by Udayana in the *Kusummanjali*, between 850 and 980 A.D., while Mādhva, founder of the Mādhva sect, left Dvaita commentaries on ten principal *Upanishads*. The Bhagavata Purana seems to have sprung from the Bhagavata community and from its influences were born a number of new sects. It has several distinctive features. It devotes itself to Krishna's boyhood and youth and to the gopis or cow-maidens; but even yet Radha does not appear, her place being foreshadowed by a favourite gopi. Further, *Bhakti* now attains its highest point of mystical expression and it must have arisen among Vaishnava ascetics. It is a surging emotion which leads to tears and laughter, to sudden fainting fits and long trances of unconsciousness. But it has one fatal feature in its sensuous description of Krishna's dalliance with the gopis. Hindus are by no means in accord as to its age or authorship, but, as Alberuni mentions it, it can hardly have been written after 900 A.D. and must be due to a community of singers in the Tamil country. The sects due to the Bhagavata Purana's influence are numerous. They included the now possibly extinct Raseshvaras or Mercurials, who acquired a divine body by the use of mercury and then by Yoga an intuition of the Supreme; the aspirant is then liberated in this life. Another inchoate sect is that of the Gorakhnathis—closely related to the Kapalikas—with an unorganized laity. They have temples all over India from the Gorkatri in Peshawar, in Nepal, right down to the south. Its adherents mainly called Kanphatas, Yogis or split-eared, are its strongest part. Both Tantrik Hinduism and Tantrik Buddhism glorify Goraksha Nath and his companion saints, yet Goraksha himself probably flourished about 1200 A.D. and with his name is associated a new type of Yoga, the Hatha-yoga, destined to attain the *samadhi*, "supreme concentration of mind," by strange bodily postures, breathing exercises and attention. In the later books on this cult is added Raja-yoga, a more intellectual discipline. The book by Goraksha on the Hatha-yoga seems to be lost.

On the other hand, some of the older sects have disappeared, e.g., the Rama sect which re-wrote the *Ramayana*, adding Shakti elements to it so that Sita's illusory self is carried off by Ravana and when Rama speaks as a man he is explained to be under the influence of *maya*, "illusion." This elevates the pair to the position of the Supreme.

Mohammedan Influences.—The earliest influences of the Muslim invasions were naturally confined to Sind, the Punjab and Hindustan. They were often unorthodox, the purer forms of the faith being too intent on the establishment of their own sternly monotheistic creed to win acceptance from Hindus. Not much before 1400 did Sufism begin to make headway in India and most of the institutions which have survived from that period are due to it. The Mohammedans certainly destroyed Hindu temples which they called Jain but more for the sake of their materials than for any other purpose. With the reign of Akbar began a new movement, namely the attempt to create a new world-religion which should unite the warring elements. This religion borrowed from all. It was never strictly defined, as Akbar was suspect to his Muslim subjects, but he was at least tolerant, which the later Aurangzeb was not. It would be as difficult to deny that his austere faith was one of the principal causes of the fall of the Moghul empire as it would be to dispute its influence on Hindu monotheism. Weak as we have seen the movement towards theism to have been, it found support from Islamic example. It was the same with idolatry. To this movement we must ascribe the teachings of Namdeva and Trilochan in the Maharashtra land, of Sadana and Beni in the north, and of Ramananda who lived from about 1400 to 1470. He was followed by his disciple Pipa and by Kabir. Ramananda seems to have been under Ramanuja's influence, yet he worshipped Rama and Sita and their attendants alone. He probably derived his doctrine from the Ramaites of the south, but he came to the north and among his personal followers were an outcast, a Mohammedan and a woman; yet he attempted no reform of caste restraints, though he mitigated some in the matter of food. The most numerous of the ascetics founded by him are

the Bairagis "passionless," or Avadhuta, "liberated," only equalled to-day in numbers by Shankara's Dasnamis. But he founded no regular sect. Indeed sectarianism was in process of decay. Ramananda still affected images, but Kabir denounced them and worshipped God (Ram) alone. Many of his sayings were included in the Sikh Granth (*q.v.*).

Of the ten sects founded by his followers during the next three centuries, the Sikhs (*q.v.*) are incomparably the most important. All are to be found in the country about Delhi, in Rajputana and its states and the Punjab, only one, the Shiva Narayanas, having originated in Ghazipur in the United Provinces. (H. A. R.)

GOVERNMENT AND ADMINISTRATION

Political Divisions.—India (including Burma) has a total area of 1,805,332 sq.m., with a population of 318,942,480 by the 1921 census. These figures comprise:—

British India.—British India; area 1,094,300; pop. 247,003,293; and Indian States; area 711,032; pop. 71,939,187. British India proper is divided into 15 provinces. Nine of them would, in point of size and population, rank with important countries in Europe. They are Assam, Bengal, Bihar and Orissa, Bombay, Burma, Central Provinces and Berar, Madras, Punjab, and the United Provinces of Agra and Oudh; each with its own local government under a governor. Then come two smaller provinces, of special strategical and military importance, which are more directly under the control of the central government, to wit, the North-West Frontier and British Baluchistan. The remaining four are lesser areas which, for administrative convenience, are technically classed as provinces, viz.: Ajmer-Merwara, the Andaman and Nicobar islands, Coorg, and the Delhi enclave.

The Indian States.—The Indian states are governed by Indian princes or chiefs, the more important of whom are helped by political officers appointed by the British government, and resident at their courts. The degree of sovereignty exercised by the different rulers varies greatly, as do the areas under their dominion. The greater princes administer the internal affairs of their states with almost complete independence, having revenues and armies of their own, and the power of life and death over their subjects. At the other end of the scale are petty chiefs with a jurisdiction hardly higher than that of an ordinary magistrate; and between these extremes lies much gradation. The authority of each ruler is determined by treaties or engagements with the British government, or by practice that has grown up in the course of their relations with British India. The paramount power requires the states not to enter into alliances or armed disputes with each other, or with foreign states; and it asserts the right to interfere in cases of gross misgovernment.

The most important states are Hyderabad, Mysore, Kashmir, Gwalior and Baroda. After them come a number of great princes, for whom the official criterion of importance is the number of guns to which they are entitled by way of salute. Some of them are in direct relation with the central government; others belong to the large territorial circles known as the Rajputana and the Central India Agencies; others again, including all the more petty chiefs, deal with the local governments whose boundaries their states adjoin. Burma contains a number of Shan states, which technically form part of British India, but are administered through their hereditary chiefs.

Frontier States.—In addition to the internal states, there are several frontier tracts of India, whose status is fluctuating or not strictly defined. In Baluchistan there are the native states of Kalat and Las Bela, and also tribal areas belonging to the Marri and Bugti tribes. On the north-west frontier, in addition to the chiefships of Chitral and Dir, there are a number of independent tribes which reside within the political frontier of British India, but over which effective control has never been exercised. The territory belonging to these tribes, of whom the chief are the Waziris, Afridis, Orakzais, Mohmands, Swatis and Bajouris, is attached to, but is not strictly within, the North-West Frontier Province. Kashmir possesses as feudatories Gilgit and a number of petty states, of which the most important are Hunza-Nagar and Chilas. Nepal and Bhutan, though independent, are under

various commercial and other agreements with the government of India. On the north-east frontier, as on the north-west, semi-independent tribes extend across the frontier into independent country. Similarly Karenni, on the Burmese border, is not included in British territory, but the superintendent of the Shan states exercises some judicial and other powers over it.

ADMINISTRATION

Government of India.—The government of India vests in the Crown, and is exercised in England by a secretary of state who, as a member of the cabinet, is responsible to parliament. His salary is now on the British estimates, which gives parliament a clearer invitation than it formerly enjoyed to discuss Indian affairs. In administrative details the secretary of state has the machinery of the India Office, and particularly the assistance of the Council of India, an advisory body with special control over finance. The members of the Council must not be fewer than eight, nor more than 12; at least one-half of them must have recently served or resided in India for ten years; and they are appointed for five years. A Hindu and a Mohammedan were put on the Council for the first time in 1907; and there are now three Indian members. Since 1920 a High Commissioner for India has been in existence. Acting as agent for the central and provincial governments in India, and also as official trade representative of the country, he occupies a position not unlike that of the accredited representatives of the Dominion governments.

In India the head of the government is the governor-general or viceroy, who is appointed by the Crown for a period of usually five years. He functions, for practically all administrative business, in his executive council; and it is in the "governor-general-in-council" that the supreme authority, civil and military, as well as the control over the local governments, vests. The "Government of India," to use its best known name, works at Delhi in the cooler months, November to April, and migrates to Simla in the Punjab hills for the rest of the year. The members of the executive council are appointed by the Crown for a period of five years; and two of them must have had ten years' service in India. There are at present seven members, including the commander-in-chief, three of them being Indians. The departments of administration are divided among them as in a European cabinet; but by use and wont the viceroy retains the portfolio of foreign affairs. All orders, however, must issue in the name of the governor-general-in-council.

In the nine major provinces the governor is appointed by the Crown; in the case of Madras, Bombay and Bengal he is usually a nominee of the political party in power in England at the time of his selection, and in the other provinces he has generally been promoted from the ranks of the civil service. Since 1921 his administration has been carried on through two agencies, the system being explained in more detail below: in certain "reserved" departments he acts with his executive council, and in the remaining ("transferred") departments with ministers. The two intermediate and the four minor provinces are each under a chief commissioner, who is directly responsible to the Government of India, and has no council.

Within the separate provinces the administrative unit is the district, of which there are 273 in India. In every province except Madras there are divisions, consisting of three or more districts under a commissioner. The title of the district officer varies according to whether the province is "regulation" or "non-regulation"—an old distinction, which now tends to become obsolete; in a regulation province the district officer is styled a collector, while in a non-regulation province he is called a deputy-commissioner. The chief non-regulation provinces are the Punjab, Central Provinces and Burma. The districts are partitioned out into lesser tracts, which are strictly units of administration, though subordinate ones. The system of partitioning, and also the nomenclature, vary in the different provinces; but generally it may be said that the subdivision or *tahsil* is the ultimate unit of administration. Broadly speaking, the subdivision is characteristic of Bengal, where revenue duties are in the background, and the *tahsil* of Madras, where the land settlement requires attention

year by year. There is no administrative unit below the subdivision or *tahsil*. The *thana*, or police division, only exists for police purposes. The old *pargana*, or fiscal division, has now but an historical interest. The village still remains as the agricultural unit, and preserves its independence for revenue purposes in most parts of the country. The township is peculiar to Burma.

The Judicial Service.—Bengal, Madras, Bombay, the old North-Western Provinces (now the Agra portion of the United Provinces), the Punjab, Burma and Bihar and Orissa, each has a high court, established by charter under an act of parliament, with judges appointed by the Crown. Of the other provinces Oudh has a chief court, and the Central Provinces, Sind and the North-West Frontier Province have judicial commissioners, all established by local legislation. From the high courts, chief courts and judicial commissioners an appeal lies to the judicial committee of the privy council in England. Below these courts come district and sessions judges, who perform the ordinary judicial work of the country, civil and criminal. Their jurisdictions coincide for the most part with the magisterial and fiscal boundaries. But, except in Madras, where the districts are large, a single civil and sessions judge sometimes exercises jurisdiction over more than one district. In the non-regulation territory judicial and executive functions are still to some extent combined in the same hands.

The chief of the Indian services is technically known as the Indian civil service. It is limited to about a thousand members, who used to be chosen exclusively by open competition in England between the ages of 21 and 24. Nearly all the higher appointments, administrative and judicial, are appropriated by statutes to this service. Other services which used to be mainly or wholly recruited in England were the education, police, engineering, public works, telegraph, forest and superior railway services. A quarter of a century ago it was estimated that, out of 1,370 appointments drawing a salary of £800 a year and upwards, 1,263 were held by Europeans; while the vast majority of the lower posts were occupied by Indians. All this is now changing fast. The pronouncement of Aug. 1917 adumbrated "the increasing association of Indians in every branch of the administration," and standard ratios for the recruitment of Indians for the different services were laid down as the result of a Royal Commission appointed in 1923. For the Indian Civil Service and the superior engineering service it will be 60 per cent; for the Police 50 and for the Forests 75 per cent; while the recruitment for the "transferred" departments will be left to the provincial governments and by them will no doubt be largely Indianized. Besides the great mass of subordinate and clerical posts, the magisterial work and the administration of the land and the revenue is very largely in the hands of Indians; the subordinate courts of justice are almost entirely manned by Indians, who also sit on the benches of all the high courts.

The Police.—The present police system, which is modelled somewhat on that of the Irish constabulary, was established by an act of 1861. It provides a regular force in each district, under a superintendent who is almost always a European, subordinate for general purposes to the district magistrate. The unit of work is the *thana* or police station; some of these have jurisdictions as big as some English counties, and staffs of not more than a dozen men. The regular force depends necessarily on the village watchmen, overworked and underpaid Dogberries, for information and help in their investigations; and they suffer from the steady failure of the general public to give them adequate support in the discharge of their duties. Though the old canker of corruption and abuse of power has not been by any means eradicated, the morale of the force has been vastly improved in recent years; and a commission appointed in 1902 led to a much needed amelioration of their pay and general conditions. The strength of the force for the whole of India is about 200,000, and its cost just under £8,000,000. A small force (about 27,000) of military police, under officers seconded from the army, is maintained along the frontiers, especially in Burma.

Jails in India are relatively cheerful abodes, and are being constantly improved. Their average population in 1924 was just over

127,000, a figure which, in its relation to the total population, is striking testimony to the general law-abiding disposition of the Indian people. Discipline is well maintained, though separate confinement has been abolished; and various industries, especially carpet-weaving, are profitably pursued wherever practicable. Diet and sanitation account for the remarkably low death rate (1924) of 14 per 1,000 inmates. A recent committee of enquiry laid stress on the reformatory side of the system; and considerable progress has been made in Borstal and similar treatment. It used to be the rule to transport to the Andamans convicts with more than six years to serve; but the islands are now being abandoned as a penal settlement, and in 1925 the number of their convict inhabitants had been reduced to close on 8,000.

Local self-government, municipal and rural, in the form in which it now prevails in India, is essentially a product of British rule. Village communities and trade guilds existed previously, but only in a rudimentary form. The present system is based upon legislation by Lord Ripon in 1882, providing for the establishment of municipal committees and local boards, whose members should be chosen by election with a preponderance of non-official members. These powers lay far too long in abeyance, but their application has been greatly stimulated as part of the recent political advance. The municipalities and district boards have largely been freed from official control; but its place has too often been taken by political faction, and it seems necessary to suspend judgment on the work of the new bodies. The chief difficulty has been to induce them to raise the taxation needed for the efficient maintenance of their services. Great and small, there are 763 municipal bodies in India, with nearly 19 millions of people under their care, and their average rate of taxation is under 9 shillings per head of inhabitant. The great cities of Calcutta, Bombay and Rangoon have energetic improvement trusts, which have worked wonders in development, removal of slums and housing projects for relieving congestion; and their example is being followed in other industrial centres. In another field of work, the Port Trusts of Calcutta, Bombay, Madras, Karachi and Rangoon have proved enlightened custodians of their harbours and the commercial interests for which they cater.

India's Constitution of 1919.—Transcending in general interest the annals of administrative routine, however progressive and benevolent, is the narrative of the development of the political machinery of a country where autocratic monarchy and internecine war had for many centuries prevailed. The restoration of peace and order under the East India Company was a task which left little leisure or inclination for theories of political emancipation; and the only duty immediately in sight was to rule the land, first, for the promotion of peaceful commerce, and then, by slow degrees, in the interest also of the people, who neither sought nor were considered fit for any share in the management of public affairs. The Mutiny set back for quarter of a century any movement that might otherwise have come from England for some measure of self-government; and it was not till Lord Ripon's viceroyalty that conceptions of political rights began to stir. Broadly speaking, they were pushed aside as being, in the eyes of the responsible officials, premature; but two consequences ensued. On the one hand, an organized school of political reformers came out into the open; the National Congress was founded in 1885. On the other hand, representatives of the people were called in to the councils of the government. The former movement progressed with vastly greater rapidity than the latter. Each succeeding year brought louder insistence on India's right to share in her own administration; while the appointment of an extra Indian here and there to the small legislative bodies was but a halting response, especially as the elective principle was steadily refused. It is sometimes said that the first big forward move towards political responsibility was forced by the outbreak of revolutionary crime in Lord Minto's regime; but it is well known that he and some of his advisers had been convinced of the need for an advance before the outrages began, and as a consequence of the remarkable outburst of political claims that followed Lord Curzon's departure.

The Morley-Minto reforms, as they are commonly called, of

1909 seemed at the time a liberal and striking advance, and were received with a chorus of approval and gratitude by Indian publicists. But they entrusted the legislatures, and through them the people with no control over the executive governments; Lord Morley himself, good radical though he was, had definitely rejected the idea that they gave parliamentary institutions in embryo. What they did do was to introduce the electoral principle into the Indian legislatures, and give them a wider sphere of influence over the executive government. But in effect the legislatures remained advisory bodies, and the absence of any administrative responsibility whetted their critical faculty without giving them any corresponding practice in the actual work of government. The executive authorities, imperial and provincial, remained governments of officials, responsible to the Secretary of State, and through him to the British Parliament, and not amenable in any direct sense to popular control in India.

From this arrangement to the announcement of 1917 was a wide step, involving organic change and not taken before time. The enthusiasm which had welcomed the Morley-Minto reform had long evaporated, and the demand by the Indian leaders for administrative power was clamorous. The Montagu-Chelmsford report conceded the justice of the demand, and proposed that responsible government, in the sense of government by ministers primarily responsible to an elected assembly, should be conferred on India by progressive stages. It recognized that India was not yet ready for full responsible government, that an electorate had to be created and that its representatives must at first be inexperienced. Its authors proposed therefore to confine the first stage of advance to the major provinces, and in these provinces to set up a dual form of government, generally known as "dyarchy." This device, accepted only after all possible alternatives had been found impracticable, was a division of the provincial field of government into two sections, one of which would be transferred to the control of ministers chosen by the Governor from the elected members of his legislative council.

In July 1919 a bill embodying this scheme, with certain modifications, was introduced into the House of Commons, read a second time and referred to a joint select committee of both Houses presided over by Lord Selborne. The committee, after an elaborate investigation, accepted the main principles of the scheme, and dealt at length with the political and administrative problems involved in the bill. The bill passed both Houses substantially as amended by the committee, and left a great deal of the new constitution to be worked out by rules drafted and applied by the government to meet the needs of each particular case. The general purport of the constitution will now be described.

At the outset it demarcates the duties of the "central" or Imperial government from those of the provincial governments. The former retains certain powers of supervision and control over the provincial administrations; but its direct functions are specifically listed, and the departments which are under the provincial governments are similarly enumerated. These governments derive their revenue from the departments under their own control, i.e., land revenue, stamps, excise, forest, etc. The Imperial government takes the yield of its own central departments—railways, post and telegraphs, customs, income tax, salt, opium, etc. At first, however, these did not balance its budget, which carries the whole cost of the defence of India; and consequently it had to levy subsidies from the provinces, though it is pledged to forgo them when the development of its own resources shall permit. As with the administrative and financial powers, so also are the law-making powers of the central and the provincial authorities carefully delimited.

Each of the major provinces is placed under a Governor. The whole of the provincial departments are divided in each province into two groups, the "reserved" and the "transferred." The former (at present law and order, justice, police, the land, etc.) are administered by the Governor and his Executive Council, the latter (education, public health, excise, etc.) are administered by the Governor and two or more Ministers, who are chosen by him from the leaders of the provincial legislature. These two

bodies work independently, each in its own field; and their responsibilities are clearly distinguished. The Governor is the link of union, and has full discretion to bring them together for joint consultation on matters of common interest. The Executive Council in its control of reserved subjects is responsible through the Government of India and the Secretary of State to the British Parliament; the Ministers in their control of transferred subjects are responsible to the legislative council on the spot. This, in the briefest terms, is the system which has been named or nicknamed "dyarchy." Its purpose is to provide a field of actual duty in which Indian leaders can be trained by actual practice in the art of Government.

The legislative council in each province has a large elected majority, with an element (under 30%) of officials and nominated members. The elections are direct and the constituencies mainly territorial. A property qualification, differing in different provinces, determines the franchise. The vote was originally given to about 5,000,000 of the adult male population in the whole of India, and has subsequently been extended by the grant of a restricted female suffrage in certain provinces. For whatever legislation and supply they require, both halves of the Government are dependent on the legislature thus constituted. In the "transferred" sphere, Ministers must secure the support of the legislature. If they fail, their policy fails; and the ordinary course is for them to resign or be dismissed by the Governor, so that they may be replaced by Ministers who can carry the legislative council with them.

In the "reserved" sphere, it is the task of the Governor and his official colleagues to reconcile the legislature to their policy. But if they fail, their responsibility for right policy to the British Parliament is in no wise diminished; certain safeguards are accordingly provided against the event of the council refusing a law or supply for which it has been asked by them. The Governor has an exceptional power to pass such a law by his own decree, if he certifies that it is essential for the discharge of his responsibility; but a measure enacted in this way has to be reserved for His Majesty's pleasure. Similarly the Government may restore a grant for expenditure which has been refused or reduced by the Council if the Governor certifies in the same sense; and in case of emergency he may authorise any expenditure which "may be in his opinion necessary for the safety or tranquillity of the province or for the carrying on of any department." Finally, should the legislature take action in any department which the Governor regards as dangerous, he has wide powers to stop a bill, or to refuse assent to it, or to return it for reconsideration, or to reserve it for the consideration of the Governor-General. Extensive safeguards thus exist against the possible misuse of its power by the provincial legislature.

The Imperial Sphere.—In the central Government there is no dyarchy. The Governor-General and his Executive Council still remain in sole and undivided responsibility to Parliament for the supreme Government of India. The central legislature, however, has been radically altered by the 1919 Act. The Lower House, or Legislative Assembly, has 144 members, 103 of whom are elected direct by constituencies similar to those which elect to the provincial legislatures but larger in area and with a higher property qualification. In the Upper House or Council of State are 60 members, of whom 33 are elected on a still more restricted franchise. In neither Chamber therefore is there an assured majority for the Government, to secure the laws, the taxation measures or the expenditure grants which it requires for the administration of the country.

It was foreseen that the Central Government may not always be able to carry the legislature with it, and machinery was provided for avoiding a deadlock in such an event.

In legislative business a difference between the two Chambers may be referred to a joint sitting. If in either Chamber a bill is proposed or amended so as to affect "the safety or tranquillity of British India or any part thereof," the Governor-General may stop it. He may also, as under the previous constitution, veto a bill, or refer it for His Majesty's pleasure. Should he recommend a bill which either Chamber accepts and the other rejects, he may

treat it as enacted; or if both Chambers reject it, he may make it into an Act on his own responsibility. In both cases, however, the Governor-General must first have certified that the "passage of the bill is essential for the safety, tranquillity or interests of British India or any part thereof," and the measure must subsequently be laid before both Houses of Parliament; effect may not be given to it, unless in a state of emergency, until His Majesty's assent has been received. In financial business the supply grants have to be voted by the Legislative Assembly; but if a grant which the Governor-General declares to be essential to the discharge of his responsibilities is refused or reduced, he may restore it.

Expenditure on defence and in the political and ecclesiastical departments, charges prescribed by law, loan charges and certain salaries and pensions need not be voted; and the Governor-General has power to sanction vital expenditure in cases of emergency.

Further Development.—The above is an outline of the complex scheme that comprises the first stage in what the preamble of the 1919 Act describes as "the gradual development of self-governing institutions." As "the time," to quote the Act again, "and the manner of advance can be determined only by Parliament," it was provided that, 10 years after the passing of the Act, a Parliamentary Commission will go to India, to inquire into the working of the reforms, and to report on the desirability of establishing the principle of responsible government or of extending, modifying or restricting the degree of responsible government already existing. Apart from the constant war, described elsewhere, that has been waged by the extreme nationalists on the constitution and all its works, there has been ceaseless agitation by the same section of politicians to have this commission appointed before 1929, in order to expedite the issue of granting their demands for provincial autonomy and Dominion status. The working of the constitution had in fact been seriously hampered by the non-co-operation movement in its earlier years, and later by the destructive tactics of the extremists in the councils; so that the material for measuring its effects could not be accumulated as the 1919 act had contemplated. Moreover the nationalists gave no response to the repeated invitations (in particular from Lord Birkenhead) to draft a constitution which they would be prepared to work. It was thus decided at the end of 1927 to appoint the statutory commission at once; and it started for India in Jan. 1928, under the presidency of Sir John Simon (*q.v.*).

EDUCATION

At no period of its history has India been an altogether unenlightened country. Inscriptions on stone and copper, the palm-leaf records of the temples, and in later days the widespread manufacture of paper, all alike indicate, not only the general knowledge, but also the common use, of the art of writing. From the earliest times the caste of Brahmans has preserved, by oral tradition as well as in mss., a literature unrivalled alike in its antiquity and in the intellectual subtlety of its contents.

The Mohammedan invaders introduced the profession of the historian which reached a high degree of excellence, even as compared with contemporary Europe. Through all changes of government vernacular instruction in its simplest form has always been given, at least to the children of respectable classes, in every large village. Even at the present day knowledge of reading and writing is, owing to the teaching of Buddhist monks, as widely diffused throughout Burma as it is in some countries of Europe.

During the early days of the East India Company's rule the promotion of education was not recognized as a duty of government.

The enlightened mind of Warren Hastings did indeed anticipate his age by founding the Calcutta *madrasa* for Mohammedan teaching, and the establishment of the Sanskrit College at Benares in 1791 was associated with the name of another servant of the Company, Jonathan Duncan. But Wellesley's schemes of imperial dominion did not extend beyond the establishment of a college for English officials.

On the 100,000 rupee grant which was prescribed, the first of

its kind, for the encouragement of education by the Charter Act of 1913, no general scheme of public instruction could be built. But the Sanskrit College in Calcutta was founded in 1824, the medical college by Lord William Bentinck in 1835, the Hooghly *madrasa* by a wealthy Indian gentleman in 1835, and the Agra college had been established in 1823. Meanwhile the missionaries made the field of vernacular education their own. Discouraged by the Official authorities, and ever liable to banishment or deportation, they not only devoted themselves with courage to their special work of evangelization, but were also the first to study the vernacular dialects spoken by the common people. Just as two centuries earlier the Jesuits at Madura, in the extreme south, composed works in Tamil, which are still acknowledged as classical, so did the Baptist mission at Serampur, near Calcutta, first raise Bengali to the rank of a literary language. The interest of the missionaries in education, which has never ceased to the present day, though now comparatively overshadowed by government activity, had two distinct aspects. They studied the vernacular, in order to reach the people by their preaching and to translate the Bible; and they taught English, as the channel of non-sectarian learning.

A fresh wind began to blow from England, with the Charter Act of 1833. The work of the missionaries received official licence; and in 1835 Lord William Bentinck decided that "the great object of the British government ought to be the promotion of European literature and science among the natives of India." This was the last word on a long-drawn controversy between a school which arrived at the extension of oriental learning in India in its own languages, and the school which urged the teaching of elementary knowledge in the vernacular tongues and of the higher branches in English. The scale had been turned by Macaulay's famous minute in support of the latter view; and the low state into which Hindu morality and culture had sunk at the time was felt to be adequate justification for the decision. It settled the aim of the British governmental system of education in India, and Sir Charles Wood's famous despatch of 1854 determined the methods and machinery. From that date onwards education has meant a network of schools, colleges and examinations ultimately controlled by the government. Many of the institutions are maintained directly from public funds, and staffed by teachers who are public officials. Another class is maintained by local authorities, subject to close control by the government. A third class under private (e.g., missionary) management depends on the government for grants-in-aid or for "recognition"; and both grants and recognition imply strict compliance with governmental regulation. At the same time the government in its anxiety to hold an even balance between the different sects and creeds in India has kept carefully aloof from the teaching of religion on morality.

The British government thus, while honestly giving its best in teachers and what it believed to be its best in curricula, exposed itself to the odium of what were for long three grave defects in the system. First, by making its own type of education the qualification for government service, it tended to concentrate the energies of the youth of India on the search for public offices, rather than of learning for its own sake or of that general development of the intelligence which would serve the industrial growth of the country. Second, the mass of students who clamoured for a purely literary education as the doorway to official employment was so great that the vast majority of them absorbed only a shallow and mechanical smattering of knowledge. To those who failed in securing government service their education proved of no commercial value: and in this way a class of unemployable and half-educated lads grew up, who became ready vehicles for political unrest and in some cases for revolutionary crime.

Third, purely secular instruction which virtually ignored the vernacular languages involved neglect of the indigenous ethos and culture of India, and became in time largely responsible for the reaction against Western civilization which characterizes recent political movements in the country.

To these defects the government was far from blind, and the history of the educational policy of the last twenty years is a constant endeavour to mitigate them. Lord Curzon had the whole

system overhauled and improved. The universities were liberalized, the colleges set on the way to becoming residential institutions, and the assistance to elementary schools largely extended; while technical and agricultural schools were reformed and vitalized. Lord Minto got a special ministry of education established; and the financial prosperity of Lord Hardinge's viceroyalty enabled him to make generous grants to the provinces for education, and to wage a definite war on illiteracy. But the root of the matter was attacked when a special commission was appointed, under the chairmanship of Sir Michael Sadler to inquire into the weaknesses of the Calcutta university, and incidentally of university education generally. It reported in 1919, and condemned in emphatic and impressive language the whole conduct of secondary and university education.

The commission advised radical reforms. The universities should be centralised, unitary, residential, teaching bodies with a government of their own. Tuition of a preparatory and not a university type should be removed to a new grade of intermediate colleges, where the curriculum would be a varied kind and would lead up to appropriate examinations not under university control though qualifying for entrance to a university, and having an independent value as a certificate of general education. Students would thus enter the universities at a later age and at a stage represented by the old "intermediate" examination, thus relieving the universities of a part of their unwieldy host of undergraduates. These recommendations were generally welcomed, and most of the former universities (including the Hindu University at Benares, which owed much to the energy of Mrs. Besant) have been reconstituting themselves accordingly, while new universities of the teaching and residential type are being built up at Dacca, Aligarh (Muslim), Lucknow, Rangoon, Patna, Nagpur and Delhi. In 1926 legislative provision was made for incorporating a university at Agra to relieve the external work at Allahabad, and in the same year a new Andhra university was inaugurated in Madras. The multiplying of universities, however, may go too far; there is already some danger of the lowering of standards, in competition for undergraduates; and it is hoped that an Inter-University Board for all India will be strong enough to maintain standards and insist on modern methods of instruction. In 1926 the number of students at university and professional colleges was 87,600 of whom barely 1½ per cent were women.

Secondary Education advances apace, and in high and middle schools of a non-technical type the enrolment in 1926 was 1,716,000 pupils, including between 8 and 9 per cent of females. Shortage of funds has interfered with the establishment of "intermediate" institutions advised in the Sadler report, as well as with the improvement of the mass of high schools. Boards of secondary and intermediate education are doing useful work in certain provinces, and vocational training is being slowly pressed forward. But the quality of the teaching still leaves much to be desired; its methods are often faulty, and it tends to be regarded entirely as a necessary gangway to the college course which will qualify for government employment or the legal profession. The moral, social and physical sides of education are insufficiently developed and it is recognized that the system calls for revision in order to make it more self-contained and adapted to the requirements of national efficiency.

Primary Education.—The pace of development here has also been seriously retarded by financial difficulties; but in 1916 the number of children at primary schools had risen to 7,800,000, inclusive of over 900,000 girls. Although it is recognized that here is the only nursery for an intelligent electorate in the future, the difficulties are many: the traditions which confine education to certain castes, communal troubles, bad communications, the dearth of competent teachers, but above all the poverty of the rural parent, who cannot spare his sons from the ranks of the bread-winners and has no belief whatever in educating his daughters. To these permanent obstacles must be attributed the fact that, according to the census of 1921, only 122 in every thousand men, and 18 in every thousand women, in the country can read and write. In face of these figures it is not surprising that the legislatures have frequently turned to the remedy of compulsion.

Acts asserting the compulsion principle have been passed in several provinces, but the translation of principle into practice is still incomplete. Meanwhile the decentralisation of the control of primary education offers a prospect of greater elasticity, especially in adapting the school curriculum to rural needs.

Female Education was long the despair of reformers. Social prejudices and the subordinate and largely extended position of women were antagonistic to it, and there was the greatest difficulty in obtaining, except in the Christian Community, qualified women teachers. The Brahmo Samaj and a few enlightened groups and individuals persevered in the education of their womenfolk: but progress was deplorably limited and slow. With the awakening of national feeling, some advance is now apparent. In 1926 it was possible for the official reporter to write that "female education and co-education in the primary classes are growing in popularity; schools and colleges for women are on the increase; women are being encouraged to take up physical training, games and vocational education; and propaganda in this excellent case is widespread." When this was written, there were just over one million females receiving college and school education in the whole of British India.

The following statistics show the progress of education between 1896-97, when Lord Curzon had not begun his measures of reform; 1921-22, when education (except in universities) was being handed over to the control of ministers under the new constitution; and 1926, the latest year for which complete figures are available.

		1896-97	1921-22	1925-26
Colleges	Institutions . . .	160	231	290
	Pupils . . .	18,783	59,595	87,589
Secondary schools	Institutions . . .	5,267	8,987	10,837
	Pupils . . .	535,155	1,239,524	1,716,147
Primary schools	Institutions . . .	103,920	160,072	183,164
	Pupils . . .	3,209,825	6,310,451	7,799,076
Training schools	Institutions . . .	184	1,072	696
	Pupils . . .	5,667	26,931	25,343
Special schools	Institutions . . .	355	2,939	8,110
	Pupils . . .	18,952	105,775	264,548
Private institutions	Institutions . . .	42,139	34,807	34,726
	Pupils . . .	568,488	639,125	621,618
Total	Institutions . . .	152,025	208,108	237,823
	Pupils . . .	4,356,870	8,381,401	10,514,321

Despite this substantial progress, illiteracy remains in complete ascendancy. At the 1921 Census, roughly 7 per cent of the population—19.8 million males and 2.8 million females—were returned as literate, in the sense of being able to read and write a letter in their own vernacular language. Literates in English were only .8 per cent of the population.

PUBLIC HEALTH

Like education, the sanitary welfare of the country is extremely backward, and for much the same reasons,—climate, general poverty and the pressure of the population. Over an average of five recent years, the ratio of births was 33.44 per 1,000 of population, and the ratio of deaths 26.56; fully one fifth of the mortality being among infants of under a year old.

In years of bad epidemics, the death roll runs much higher; the ratio, for example, was 62.46 in 1918, the disastrous influenza year; and plague, which started in 1896, has carried off 12 millions in the last decade. Cholera is endemic in some areas, malaria in almost all; hook-worm and *kala azar* are widespread. Medical relief hardly exists outside the towns, except at the dispensaries established by the government and now controlled by local authorities. Yet improvement is being slowly effected. In the past, every important fair or seat of pilgrimage was a focus of disease and death to many thousands. This has now been brought under control; and great strides have been made in providing the cities and larger urban areas with a supply of pure drinking water and with proper sewage or conservancy. Elementary hygiene is also being introduced into the teaching in schools; and some interest is being taken in child welfare. In British India there are about 4,000 hospitals and dispensaries of very varying

quality, at which 41 millions of patients were treated in 1925; but the total number of beds available was only 45,000.

FINANCE

Sources of the Revenue.—For a country where the opposition to direct taxation is so strong as it is in India, the share which it takes in the national revenue is now highly creditable. While indirect taxation is levied through the Customs, on salt, by stamps and otherwise, the direct imposts are the taxation on incomes other than those derived from land, and the land revenue, round which an ancient controversy rages, as to whether it is a tax or a rent. As the land revenue is the oldest, and used to be by far the most important element in the State's income, some description of the machinery for assessing it seems desirable, especially as it is unique to India and as no field of government policy has been more hotly canvassed in the past.

That the state should appropriate to itself a direct share in the produce of the soil is a fundamental maxim of Indian finance that has been recognized from time immemorial. In the old Hindu village community, the land was not held by private owners but by occupiers under the petty corporation; the revenue was not due from individuals, but from the community represented by its head-man. The aggregate harvest of the village fields was thrown into a common fund, and before the general distribution the head-man was bound to set aside the share of the state. No other system of taxation could be theoretically more just, or in practice less obnoxious to the people. Under the Mogul empire, as organized by Akbar, the share of the state was fixed at one-third of the gross produce of the soil; and a regular army of tax-collectors was permitted to intervene between the cultivator and the supreme government.

Shah Jahan and Aurangzeb extracted a larger land revenue than the British do. When the government was first undertaken by the East India Company, no attempt was made to understand the social system upon which the land revenue was based. The joint responsibility of the village community for the revenue was overlooked, and the convenience of collecting it from some individual or group was magnified. The conception of private property in the soil, with which the early British authorities were familiar at home, was grafted from a rural policy to which it was wholly alien. As a result, the office of *zamindar*—originally a mere farmer or lessee of the revenue under the Mohammedan régime—was transmuted into that of landowner and zamindars were created, where they did not exist, from men or families who, for almost any reason, were prominent in the areas of their residence.

The annual government demand was made the first liability on the land; subject thereto, the registered land-holder was given powers of sale or mortgage scarcely more restricted than those of a tenant in fee-simple. At the same time the possible hardships, as regards the cultivator, of this absolute right of property vested in the owner were anticipated by the recognition of occupancy rights of fixity of tenure, under certain conditions. Legal rights were substituted for unwritten customs; and the new class of landowner was endowed with a credit which he never before possessed, by allowing him a certain share of the unearned increment. Against the misuse of this credit the British government has had consistently to struggle.

The means by which the land revenue is assessed is known as settlement, and the assessor is styled a settlement officer. In Bengal the assessment has been accomplished once and for all, but throughout the greater part of the rest of India the process is continually going on. The details vary in the different provinces; but, broadly speaking, a settlement may be described as the ascertainment of the agricultural capacity of the land. The settlement officer estimates the character of the soil, the kind of crop, the opportunities for irrigation, the means of communication and their probable development in the future, and all other circumstances which tend to affect the value of the produce. With these facts before him, he proceeds to assess the government demand upon the land according to certain general principles, which vary in the several provinces. The result is the settlement report, which records, as in a Domesday Book, the entire mass of

agricultural statistics concerning the district.

Lower Bengal and a few adjoining districts of the United Provinces and of Madras have a permanent settlement, the land revenue having been fixed in perpetuity by Lord Cornwallis in 1793. The zamindars of that time became practically landlords, with rights of transfer and inheritance, subject to the payment of a rent charge in perpetuity. But no detailed record of tenant-right was inserted in the settlement papers, and the cultivators lost rather than gained in security of tenure. The peasantry found no protection in the law courts until 1859, when an act was passed which restricted the landlord's powers of enhancement. Later the Bengal Tenancy Act of 1885, since amended by an act of 1908, created various classes of privileged tenants, including one class known as "settled ryots" in which the qualifying condition is holding land, not necessarily the same land, for twelve years continuously in one village. Outside the privileged classes of tenants the act gives valuable protection to tenants-at-will; and the original vices of the Bengal system are being partly overcome, though the growing division of rights in the land is an abiding economic calamity.

The Ryotwari System.—The prevailing system throughout the Madras presidency is the ryotwari, which takes the cultivator or peasant proprietor as its rent-paying unit.

The representatives of several ancient lines of powerful chiefs exist in the extreme south and in the north of the presidency. Their estates have been guaranteed to them on payment of a peshkash or permanent tribute, and are saved by the custom of primogeniture from the usual fate of subdivision. Throughout the rest of Madras there are no zamindars either in name or fact. The influence of Sir Thomas Munro led to the adoption of the ryotwari system, which will always be associated with his name. According to his system, assessment is made with the cultivating proprietor upon the land taken up for cultivation year by year. Neither zamindar nor village officer intervenes between the cultivator and the state, which takes directly upon its shoulders all the landlord's responsibility.

Nothing can be more complete in theory and more difficult of exposition than a Madras ryotwari settlement. First, the entire area of the district, whether cultivated or uncultivated, and of each field within the district is accurately measured. The next step is to calculate the estimated produce of each field, having regard to every kind of both natural and artificial advantage. Lastly, a rate is fixed upon every field, which may be regarded as roughly equal to one-third of the gross and one-half of the net produce. The rates thus ascertained are fixed for a term of thirty years; but during that period the aggregate rent-roll of a district is liable to be affected by several considerations, which are discussed and decided by the collector at the *jamabandi* or court held every year for definitely ascertaining the amount of revenue to be paid by each ryot for the current season.

In the early days of British rule no system whatever prevailed throughout the Bombay presidency; and even at the present time there are tracts where something of the old confusion survives. The modern "survey tenure" as it is called, dates from 1838. Each field is measured, and assessment placed upon it according to the quality of the soil without any attempt to fix the actual average produce. This assessment holds good for a term of thirty years.

In Other Provinces.—In the other provinces variations of the zamindari and ryotwari systems are found. In the United Provinces and the Punjab the ascertainment of the actual rents paid is the necessary preliminary to the land revenue demand. In the Central Provinces, where the landlords (*malguzars*) derive their title from the revenue settlements made under British rule, the rents are actually fixed by the settlement officer for varying periods. In addition nearly every province has its own laws regulating the subject of tenancy.

The principles of the land revenue settlement and administration were reviewed by the government of India in a famous resolution prepared under Lord Curzon's direction and presented to parliament in 1902. It gives a full description and justification of the system and its consequences. In the previous year, the

Famine Commission had come to the general conclusion that "except in Bombay, where it is full, the incidence of land revenue is low to moderate in ordinary years, and it should in no way *per se* be the cause of indebtedness." There is now an active movement to have the principles of valuation and assessment fixed by law instead of being left to usage. In areas where enhancements in the land revenue are decided to be, in whole or part, attributable to the benefits of State irrigation, an appropriate part of the field is transferred to the irrigation department. Otherwise that department charges by a rate on the land for the water it supplies, attempts to meter the flow and charge accordingly having so far met with imperfect success.

Income Tax.—Income derived from land has always been immune from the income-tax, which was first imposed in 1886, as well as from the more recent super-tax. Intensely unpopular and difficult to assess, this source of revenue has steadily been developed in recent years, and whereas the gross receipts from it twenty years ago did not exceed £1,500,000 they are now in the vicinity of £14,000,000. The present rate of income tax ranges, on incomes of Rs. 2,000 and upwards, from 2½% to 9%, the latter being the rate on companies. The super-tax falls on everything over Rs. 50,000 of the total income; it is 6½% for companies and is graded upwards in the case of individuals.

Salt.—Prior to the successive reductions of the salt duty in 1903, 1905 and 1907, next to land, salt contributed the largest share to the Indian revenue. Broadly speaking the salt consumed in India is derived from four sources: (1) importation by sea, chiefly from England and the Red Sea and Aden; (2) solar evaporation in shallow tanks along the seaboard; (3) the salt lakes in Rajputana; (4) quarrying in the salt hills of the northern Punjab. The salt lakes in Rajputana have been leased by the government of India from the rulers of the states in which they lie, and the huge salt deposits of the Salt Range mines are worked under government control, as also are the brine works on the Runn of Cutch. The duty on salt, which was once regarded as financial reserve for war, has often been altered and now stands at Rs. 1½ per *maund*, or just over one farthing per lb.

Opium.—The importance of opium as a source of revenue is steadily diminishing, the area under poppy cultivation having shrunk from 207,000 acres in 1918 to 71,000 acres in 1926, and being still further reduced. The drug is manufactured from (1) poppy grown under government supervision in certain districts of the United Provinces, and (2) poppy grown in certain Indian states and yielding what is known as Malwa opium. It used to be largely auctioned for private export to China and elsewhere. But the attempts at social reform in China and the intervention of the League of Nations have led to a profound modification of the system; and cultivation is being regulated with a view to the extinction of the export trade by the end of 1935. A certain amount of opium is also sold to provincial governments for local consumption in India; and attempts are being made to develop the market for the medicinal products of the drug.

Customs has already been discussed. Excise duties vary greatly in different provinces, and flow from a special form of government monopoly. The articles taxed are intoxicants and drugs; and the avowed object of government is to check consumption as well as to raise revenue. The right to manufacture, and the right to retail, spirits and beer are monopolies of government permitted to individuals only upon terms and under strict supervision. Of excisable drugs the most important are opium, bhang, ganja and charas. Opium is sold through private retailers at a monopoly price. Bhang, ganja and charas are three different narcotic drugs prepared from the hemp plant (*Cannabis sativa*, var. *indica*).

The plant grows wild in many parts of India; but the cultivation of it for ganja is practically confined to a limited area in the Rajshahi district of Bengal, and charas is mainly imported from Central Asia.

In regard to ganja and charas, cultivation of the plants is severely restricted and a direct quantitative duty is levied on the drugs on issue from the warehouse in the province of consumption; while as regards bhang, cultivation of the hemp for its production is prohibited or taxed, and collection of the drug from

wild plants permitted only under licence, a moderate quantitative duty being levied in addition to vend fees. No duty whatever is now levied upon tobacco in any part of India. The plant is universally grown by the cultivators for their own smoking, and the impossibility of accurate excise supervision has caused the government to abandon the impost. Other sources of revenue are stamps, levied on judicial proceedings and commercial documents; registration of mortgages and other instruments; and provincial rates, chiefly in Bengal and the United Provinces for public works or rural police.

Provincial Share in the Revenues.—Prior to the 1919 constitution, the resources of the State used to be divided, by a sort of variable contract, between the central government and the provincial governments. Part of the 1919 reform was the complete severance of the central from the provincial finances: from 1833 up to 1921 they had been amalgamated; from the budget for 1921-22 onwards they were separated. Under this arrangement the nine major provinces now receive and dispose of over £50,000,000 of receipts, representing their collections of land and irrigation revenue, excise, stamps and forest income. It is spent by them on their administrative business, justice, education, public works, police and gaols, public health, etc. In other words, the local governments receive the yield of the sources which they administer, and are responsible for the expenditure of the provincial departments, both reserved and transferred. In order to enable local governments to discharge their new functions, they have been given powers of taxation, scheduled so as not to invade the sphere earmarked for the requirements of the central government. They have been authorised to raise loans, either through the central government or independently, and some of the provinces have already borrowed for works of improvement such as irrigation and city development schemes. At the outset, the central government found itself no longer in control of funds sufficient for its own business. The customs, salt, opium and net railway receipts, income tax, etc., when they ceased to be supplemented as before by a share of the provincial land revenue, stamps and excise receipts, etc., proved inadequate to meet the demands of defence, the public debt and the other central liabilities. It was thus necessary to impose a levy on the provinces, admittedly as a temporary measure pending the inevitable expansion of the central revenues. The provincial legislatures fastened on the arrangement as the main cause of their own financial stringency, and magnified a not unreasonable expedient into an intolerable grievance, under cover of which there has been a tendency to evade the imposition of taxation that might have balanced their own budgets. From 1928 however the levy ceased, and on the horizon will soon appear a new controversy as to how the central government should share its own surplus with the provinces. Meanwhile local governments claim, in addition to their own separate revenues, a share of the taxation upon income collected within their boundaries; and some concession on this point has been yielded as an exception to the general rule of separate resources, by giving each province three pies for every rupee by which the income assessed within the province exceeds the income that was similarly assessed in 1920-1.

Local Finance.—The 767 municipalities of British India have the disposal of an annual revenue of £12,000,000 excluding abnormal items and borrowings; and the district and local boards have a normal revenue of about £10,500,000. Both classes of bodies have been endowed by the 1919 constitution with a financial independence commensurate in its degree with that of the provinces. The six port trusts have statutory powers for their own business, and calculate an income of approximately £6 millions: Bombay and Calcutta in particular having raised considerable loans, which rank in the Indian market only second to government securities.

Recent Financial History.—Before the war India was making rapid economic progress. After the famine year of 1908 the monsoons were satisfactory and the harvests good; trade went well, and there were large windfalls in the opium revenue. During the five years immediately preceding the outbreak of war the country absorbed gold and silver to the amount of £127 millions.

Large grants became possible to the provinces for education and public health; some notable new undertakings were launched, and a spirit of enterprise was displayed in commerce and in industry. When the world went to war in 1914, Indian finance enlarged its experiences. Direct expenditure on the war was at first small, but the country's external trade was dislocated, and her railway and customs receipts suffered accordingly; so that the first two years were marked by deficits. In 1916-7 additional taxation was imposed, while the export of war material had now begun to assume large proportions, and agriculture was also flourishing. In 1917 the financial position was sufficiently strong to justify the Indian government, with approval of the Legislative Council, in a contribution of £100,000,000 to the home government towards the cost of the war; and in 1918 a further contribution was volunteered, which had, however, to be subsequently revised after the Afghan War, and was adjusted finally at about £14,000,000. In 1917-8 taxation was again increased, but such was the activity of trade and the general prosperity of the country that a surplus of £8,000,000 was realised.

Then the tide turned, and for a series of years the national accounts failed to balance. The old standard of military expenditure was doubled; the Afghan War of 1919 and the succeeding troubles in Waziristan threw a heavy burden on the revenues; the trade boom which had been stimulated by the heavy manufacture of war material slowly exhausted itself, and exchange was crumbling; while a rapid rise in the cost of living left the government with no option but to make some corresponding increase in the wages of its army of employees. The deficits were met by temporary expedients which had recently been strangers to the Indian financial system—dipping into balances, accommodation from the banks and borrowing for revenue purposes. There followed two weak monsoons, and the year 1921-22 closed with over £22,000,000 to the bad; and, what was even worse, the government had to budget for a further deficit in 1922-23, the legislature having rejected several of its proposals, among which a rise in the salt duty was prominent for improving the revenue.

Sharp retrenchment had now become imperative, and in the winter of 1922 a special committee under Lord Inchcape attacked the whole problem of expenditure. Their recommendations, drastic and comprehensive, extending to military as well as to civil charges, were put into effect, as far as time admitted, in the estimates for 1923-24, and the salt tax was doubled in the face of fierce opposition. The result, combined with a marked revival in trade, was a small surplus at the end of the year. The budget for the succeeding year was wrecked by an extremist demonstration in the Assembly; and the Viceroy had to exercise his emergency powers of restoring it, though he was careful to revert the salt tax to its old rate of Rs. 1½ per maund. Despite this untoward start, 1924-25 went well; trade steadily improved, and with it exchange revived, the year ending with a substantial surplus. The same was true of 1925-26, a year of good harvests, though external trade was hampered by the low level of agricultural values as compared with the high prices of imports. In the two following years, the world's exchanges became more stable, the country's external trade markedly advanced, and good harvests continued. Thus it was impossible, for the fifth year in succession, to frame a prosperity budget in the spring of 1928 for the financial year 1928-29. Instead of aiming at a surplus, it used its estimated excess of revenue in cancelling, for good and all, the former levies from the provinces. Its main features are:—

Source	Revenue	Object	Expenditure
	£ Millions		£ Millions
Customs	37·5	Defence	43·5
Taxes on income . . .	12·8	Debt services	11·1
Salt	5·2	Civil administration .	8·8
Opium	2·6	Other heads	9·0
Contribution by railway	4·1		
Other heads	10·2		
	72·4		72·4

It will of course be understood that none of the "nation building" services are provided for here, as they are all charged on provincial revenues. It will also be noted that effect has been given to an arrangement arrived at in 1924-25, by which the railway finances are separated from the general account. The railways are now a self-regulating entity, instead of a handmaid to the general revenues, and the sport of their vicissitudes. In exchange for this liberty, they contribute to the exchequer 1% on the outstanding capital of the commercial lines, *plus* one-fifth of whatever surplus remains after this payment, *minus* the loss incurred on the working of the strategic lines.

Indebtedness of India.—The Government of India borrows both locally in rupees and in England in sterling—the former now to a very much larger extent than before the war. The position at the beginning of the war was thus described officially:—

"Out of a total debt equivalent to £274,000,000 outstanding at the end of March 1914, only about £13,000,000 represented ordinary or unproductive debt. The annual interest on the latter was £750,000 only, and on the productive debt about £8,500,000, so that our total interest charges amounted to some £9,250,000. Railways and irrigation works in the same year yielded us a return of £15,250,000. Thus we had left some £6,000,000 of clear revenue from our great capital undertakings, after meeting interest charges on our entire public debt."

This was the result of a long, careful policy of converting unproductive debt, *i.e.*, money raised for military purposes and the like, into productive debt, by the device of short borrowing for the capital required on railways and irrigation. It had put India into a very strong position to face the changes brought about by the war. The war debt, as well as the borrowing necessitated by the series of budget deficits, all went to swell the volume of the unproductive debt; and on March 31, 1926, the total indebtedness of India was:—

<i>In India</i>		Crores of rupees
Loans		372.30
Borrowed from the paper currency reserve		31.94
Other obligations		127.94
		532.18
<i>To England</i>		£ millions
Loans		272.32
Other obligations		72.25
		344.57

Of the total it was considered that only 18% was unproductive. The productive loans included the capital liabilities for irrigation, which were taken over by the provinces when that subject became wholly provincial. The "other obligations" are mostly unfunded debt, such as post-office cash certificates and savings bank accumulations, provident funds, etc.; while in England £54,790,000 are accounted for by capitalising liabilities which are being liquidated by certain terminable railway annuities. In lieu of a general sinking fund an annual sum is appropriated from revenue for the reduction or avoidance of debt; it is now calculated at four crores plus one-eightieth of the amount by which the outstanding debt of the year exceeds the debt outstanding on March 31, 1923.

CURRENCY AND EXCHANGE

The foundation of the currency system is the rupee (16 annas or 192 pies), a coin weighing 180 gr. and containing 165 gr. of pure silver. The subsidiary coinage comprises pieces of silver, nickel and bronze; all being legal tender up to one rupee only, except the 8-anna piece, which, like the rupee itself, is legal tender without limit. Alongside of these is a paper currency, at first of slow and lingering growth, in the form of Government currency notes; the favourite notes are for 1, 5, 10 and 100 rupees, but there are also others for 2½, 20, 50, 500, 1,000 and 10,000 rupees. The note circulation as a whole is backed, as to more than one-half, by a reserve of gold and silver, and as to the balance by Government securities held partly in England and partly in India, with a margin for seasonal expansion based on trade bills

up to a strictly defined amount.

The exchange value of the rupee follows the ordinary economic law and depends on India's trade balance with the outer world. When there is a surplus of exports, import bills are at a premium and the rupee rises in terms of sterling; when in bad years exports decline and there is a relative glut of import bills, the rupee falls in terms of sterling. The operation of this law, however, assumes a fairly constant adjustment of the volumes of currency to the requirement of trade. If there were no restriction on the output of rupees, the gold value of the coin would tend to fluctuate with the gold value of silver. Up to 1873, although the Indian mints were open, the rupee continued steady at an exchange value of 2s.; then the price of silver began to tumble until the rupee dropped almost to 1s., and so disastrous were the consequences to the finances of the country that in 1893 it was decided to close the mint to free coinage and establish a "managed" currency, with the rupee as a token coin. By this policy an equilibrium was sought.

The Rupee During the War.—By the beginning of the war this system had reached considerable strength. The rupee had been given by law a parity of 16d., and trade conditions had never put it beyond the power of the Government to maintain the exchange at approximately that figure. The machinery for managing the currency was simple. The Indian Government bought silver and coined rupees to meet the requirements of the country. So long as silver was under 43 d. an oz. there was a profit on the operation, which was placed to the gold Standard Reserve. Against this reserve the Government of India could sell sterling drafts (technically known as "reserve Councils"), if the exchange value of the rupee threatened to fall. On the other hand, if it were rising, the Secretary of State could increase his normal sales of rupee drafts on India (technically known as "Councils"). Should this fail to check the rising exchange, it was generally possible to count on a free importation of private gold which would either pass into circulation or be presented to the Government for the purchase of rupees. All these arrangements were working smoothly in 1914. The Gold Standard Reserve stood at £26,000,000. The paper Currency Reserve had £24,000,000 in gold or gold securities, and the note circulation had risen to 66 crores (£44,000,000). With the War came new and disturbing demands. India was called upon to supply the British Government and the Allies with immense quantities of raw materials, manufactured goods and food-stuffs for War purposes, and also to provide funds in India and in countries where Indian troops were fighting. The Indian Government had therefore to disburse a rupee currency in very large amounts, and was compelled to increase the note issue without a corresponding increase of rupees held against the notes. The notes were convertible and their encashment drained away the reserve stock of rupees. The time drew near when either inconvertibility must be declared or silver obtained in large quantities for coinage.

The political effects of inconvertibility were regarded with grave anxiety; but in 1918 the U.S.A. came to India's aid, by passing the Pittman Act and selling 200 million ounces of its silver dollar reserve to the government of India. From July 1918 onwards American silver began to arrive in large quantities and was coined into rupees. For some months the new money went out of the reserves as fast as it was coined, but by Dec. 1918 the convertibility of the note issue was secured. Within a few months the output of the mints was represented by the enormous quantity of 1,390 million new rupees (£93,000,000) as currency.

Throughout this struggle another anxiety grew apace, in the risk of being unable to maintain the rupee as a token coin at its statutory parity with sterling. Sterling was depreciating and silver was rapidly appreciating. As the conversion of the rupee into bullion became profitable when silver touched 43d., the rapid rise beyond that figure led to a wholesale melting down of rupees for clandestine export; and the Government was forced to protect itself by hurriedly pushing up the parity of the rupee until it stood at 2s.4d. in Dec. 1919, while for a short time private remittances fetched over 2s.10d.

The whole problem was then referred to a committee of cur-

rency and banking experts sitting in London. Reporting early in 1920, this body (with one notable dissident) recommended that the rupee should be correlated to gold, and not to sterling, and that it should be given a new statutory ratio equivalent to one-tenth of the gold contained in a sovereign. Accordingly, in Sept. 1920 the Indian Coinage Act established the new ratio of the rupee as one-tenth of a gold pound. But currency was already laughing at the law. There was a rush of remittances to England, and at the same time the export trade of India fell off. The former surplus of exports gave place during the second half of 1920 to a large adverse trade balance which had to be liquidated by bills on London. Exchange persistently dropped from 2s.6d. the rupee, which in the first months of 1920 roughly represented the parity of one-tenth of a gold sovereign, to below 1s.4d. in the early part of 1921, and the price of silver receded to 32d. the ounce. All attempts by the government to maintain the rupee at its statutory parity were defeated, and exchange had to be left to find its own level. At last, another enquiry—on this occasion by a Royal Commission—was instituted towards the end of 1925. On its report, published in 1926, is based the present currency and exchange policy of the country. What was established was a gold bullion standard, under which the rupee is fixed by law at the equivalent of 1s.6d. gold, its fluctuations being confined between the upper and lower gold points corresponding to that ratio. The maintenance of the ratio was, the Commission advised, to be the duty of a Reserve Bank, and was to be secured by laying on the Bank the obligation to buy and sell gold without limit at rates fixed to accord with the gold parity of the rupee. The Bank was to be the government banker, and to undertake the Government's remittances. It was also to be entrusted with the issue of notes, to replace the present currency notes, the notes ceasing to be convertible by law. The sovereign and half-sovereign were to be no longer legal tender; and thus the old attempts to introduce a gold circulation were finally condemned. Action on those recommendations was taken by the government of India as far as lay in its power, but on the creation of a new Reserve Bank the legislature raised questions of mechanism and control which, after prolonged discussion, forced the government to abandon that part of the scheme for the present. Meanwhile, the improvement in general economic conditions has strengthened the hands of the government in securing the new legal value of the rupee. In 1925-26 the daily telegraphic transfer rates between Calcutta and London averaged 1s.6-08d.; and in 1926-7 the average was 1s.5-902d. In this article accordingly the new ratio has usually been adopted for the conversion of rupee figures into sterling; a lakh (Rs. 100,000) being treated as equal to £7,500, and a crore (100 lakhs) to £750,000.

The strenuous efforts made during the War to preserve the convertibility of the currency notes were rewarded by a rapid expansion of their popularity. The circulation (66 crores) of March 1914 has trebled, for it touched 200 crores in Aug. 1926, notwithstanding the practical disappearance of the 2½-rupee and the 20-rupee notes. In 1920 the whole system was improved by the Paper Currency Amendment Act of that year, which allowed an unlimited note issue provided a metallic basis of 50% was observed, required the gold backing to be held in India and introduced the principle of a certain definite expansion of the note issue during the busy season against trade bills of a duration not exceeding 90 days. Before the note circulation became so firmly established as it now is, several attempts were made to lighten the task of supplying India with silver currency by the employment of gold. Among them was the opening of a branch of the British Mint at Bombay, intended to coin sovereigns and 15-rupee gold pieces. Like all other similar experiments, it was defeated by the immediate disappearance of gold into the hoards of the people. Nearly 3,500,000 gold coins were minted at Bombay in 1918-19, and work was then abandoned.

The close of the World War was marked by a great outburst of speculation. The aggregate authorised capital of new joint stock companies floated in the year 1919-20 alone was Rs. 281 crores, whereas the paid-up capital of all registered companies in existence in 1914 was only 75 crores. Subsequent liquidations

were heavy. The most important of the new projects which failed to realise expectations was the Tata Industrial Bank, founded to finance new industries on much the same lines as those followed by the "D Banks."

Tariffs and Protection.—From 1894 there was a general standard customs duty of 5% *ad valorem*, with certain exemptions and certain exceptions; it was levied entirely for revenue purposes. Cotton goods were taxed at 3½%, whether imported or woven in Indian mills. During the war financial exigencies drove up the standard rate to 7½%; and in the post-war slump it rose further to 11%, with 20% on certain luxury articles. Then came the new political constitution, with its pronouncement in favour of allowing India to choose its own fiscal policy. It was speedily followed by the appointment in 1921 of the Indian Fiscal Commission, which reported for "rapid industrialization by means of discriminating protection." Coinciding as this did with a prominent tenet in the nationalist creed, the recommendation was quickly put into practice, and an Indian Tariff Board was appointed in 1923 to deal with applications for protection. The first and most important of these was from the steel industry; and in the event the Tata enterprise was protected by a heavy tariff supplemented for some years by subsidies. The tariff schedule is now a complicated document, divided into non-protective duties and other duties ranging from 2½% to 30% *ad valorem*. The distinction is subtle, seeing that some of the "non-protective" duties are as high as 25% (rough sugar) and 75% (cigars). The Board have recently decided against a general protective duty on coal. Besides the import duties, there are some low export dues on jute, hides and rice. The objectionable excise formerly levied on cotton goods manufactured in the country was removed in 1925, and the 11% duty on imported cloth became undisguisedly protective.

Labour Organisations and Legislation.—There has recently been a remarkable increase of class consciousness among Indian urban workers. Trade unionism on British lines made its first appearance in Madras during the war, the pioneer society, the Madras Labour Union, being a fairly solid organisation of the cotton-mill operatives, which quickly found imitators. The great rise of prices and the industrial boom of 1919 furnished the most favourable possible conditions for a rapid advance of trade unionism. Bombay was the chief storm centre. The cotton operatives in particular showed unsuspected staying power, and not only secured advances during the boom which meant an increase in real as well as nominal wages, but also, in 1925, won a more remarkable victory in resisting successfully a reduction of wages during the slump. Indian trade unions are still largely dependent on the help of outsiders as organisers, and the success of particular unions mainly depends on the single-mindedness with which these voluntary associates work for the material benefit of the members. An Act intended to recognize trade unionism, and to encourage it on sound lines, came into force on June 1, 1927, and the movement is going to be a permanent and growing element in Indian industrial life.

India was represented at the International Labour Conference at Washington, which was followed by an "All India Industrial Welfare Congress" held in Bombay in April 1922. Important labour legislation was enacted in the same year. The Factories Act of 1922 raised the age of admission for children from 9 to 12, for full time work from 14 to 15, prohibited night work for women, and enacted for all workers a maximum day's work of 11 hours and a maximum week of 60 hours. The Mines Act of 1923 forbade the employment of children and young persons below ground, while still permitting that of women, and limited the week's work to 60 hours above ground and 54 hours below. The Workmen's Compensation Act of the same year allowed compensation for death or accident for 3,000,000 industrial workers. The contention that long hours of labour are more tolerable and justifiable under Indian than under European conditions springs from interested motives, and is not based upon actual fact.

Foreign Trade.—The trade of India with foreign countries is conducted partly by sea and partly across the land frontiers; but the frontier trade, though capable of much extension, is only

a small fraction of the whole. The sea-borne trade is carried on chiefly through the four great ports of Calcutta, Bombay, Karachi, and Rangoon, of which Calcutta serves the fertile valley of the Ganges and Brahmaputra, Bombay serves the cotton-trade of western India, Karachi exports the wheat crop of the Punjab, and Rangoon the rice crop of Burma. Madras with its artificial harbour serves southern India, and Chittagong is rising into prominence as the point of departure for the tea and jute of eastern Bengal and Assam. The land trade is carried on with Persia, Afghanistan, Nepal, Tibet and western China.

A review of Indian trade is annually presented to parliament, and therefore it is only necessary here to mention the main channels that it has taken of recent years. The chief exports, in order of their importance today, are raw cotton, cotton goods and yarn, raw jute and jute-manufacture, food grains including rice, oilseeds, tea, hides and skins, lac, wool and rubber. Japan and China are India's best customers for raw cotton, Great Britain for raw jute, Ceylon and Germany for rice. The total value of Indian produce and manufactures exported by sea in the year 1925-6 was Rs.375 crores, of which the United Kingdom took roughly 78 crores, Japan 57 crores, the U.S.A. 40 crores and Germany 27 crores. The chief articles of import, again in order of their importance today, are cotton manufactures, which lead by a long way, metals and manufactured metal, machinery and mill work, sugar, mineral oils, railway plant and rolling stock, hardware and motor vehicles. In 1925-26 the sea-borne imports of private merchandise were valued at 226 crores, of which the United Kingdom provided 115 crores, and no other single country more than 18 crores, which was Japan's share.

Besides ordinary merchandise, there is a rarely interrupted influx of gold and silver into India. Their net import in 1925-26 was in the neighbourhood of 52 crores: but the figure varies enormously from year to year, being in effect the balancing factor in India's foreign trade, after provision has been made for what are loosely called her "home charges," *i.e.*, the interest on capital borrowed abroad, the payments abroad for her civil and military services and pensions, and the upkeep of the India Office.

Of recent years there have been significant changes in the trend of the overseas trade. There has been a marked reduction in the volume of imports, most marked in cotton goods and other textiles; but from this decline, in spite of protective duties, iron and steel have been exempt, the increase in Indian production being no greater than the increase in Indian demand; and there has been a very great increase in the imports of machinery and mill work. Other imports which have greatly increased are mineral oil and motor-cars. The volume of exports is now at least at as high a level as before the War; but the character has considerably altered. Less grain is being exported and more tea; much less raw jute and a great deal more manufactured; the export of raw cotton has increased, and so has that of cloth, particularly coloured piece-goods, but the export of yarn has greatly declined. India has in fact become much more self-sufficing with regard to manufactures, and less disposed to export food and raw materials except where, as in the case of cotton, high prices and increased production make export specially profitable. The causes of this change are partly to be found in higher freights and higher import duties; partly also in the changed condition of world trade as a whole, regarded as an interchange of manufactures for foodstuffs and raw materials, in consequence of which the Indian peasantry get only a small increase of price for most of the things they sell, but have to pay a great deal more for what they buy. But it is also partly due to Indian progress in manufacturing equipment and industrial organisation.

Local trade is conducted either at the permanent bazaars of great towns, at weekly markets held in certain villages, at annual gatherings primarily held for religious purposes, or by means of travelling brokers and agents. The cultivator himself, who is the chief producer and also the chief customer, knows little of the great towns, and expects the dealer to come to his own door. Each village has at least one resident trader, who usually combines in his own person the functions of money-lender, grain dealer and cloth seller. The money-lender deals chiefly in grain and in

specie. In those districts where the staples of export are largely grown, the cultivators commonly sell their crops to travelling brokers, who re-sell to larger dealers, and so on until the commodities reach the hands of the agents of the great shipping houses. The wholesale trade thus rests ultimately with a comparatively small number of persons, who have agencies, or rather corresponding firms, at the great central marts. Buying and selling in their aspects most characteristic of India are to be seen, not at these great towns, nor even at the weekly markets, but at the fairs which are held periodically at certain spots in most districts. Crowds of petty traders attend, bringing all those miscellaneous articles that can be packed into a pedlar's wallet; and the neighbouring villagers look forward to the occasion to satisfy alike their curiosity and their household wants.

THE INDIAN STATES

The relations now subsisting between the Indian states and the British Government are the outcome of an evolutionary process which still continues. The Mutiny, the passing of the East India Co. and the grant of *saukshya* of adoption to the rulers in 1862 obliterated the peril of annexation, breached the barriers of isolation and inaugurated for the states a new era of union under the Crown. Queen Victoria's proclamation of 1858 announced to the "Native Princes of India" that all treaties and engagements made with them would be scrupulously observed and that their rights, dignity and honour would be respected. What degree of sovereignty was thus guaranteed to the different princes and chiefs, it would not be easy to describe. As Sir Henry Maine said: "There may be found in India every shade and variety of sovereignty, but there is only one independent sovereign, the British Government. . . . The mode or degree in which sovereignty is distributed between the British Government and any Native State is always a question of fact which has to be separately decided in each case, and to which no general rules apply." Two important principles have, however, been laid down by statute, namely, first, that the Indian states "have no connections, engagements or communications with foreign powers," and second, that the British Government has the right to protect and govern subjects of the states when resident or found abroad. For international purposes, therefore, state territory is in the same position as British territory, and state subjects as British subjects.

Status of the Princes.—The assumption of the Government by the Crown in 1858 called the princes to greater responsibilities as well as to higher honours. Lord Curzon speaking at Gwalior in 1899 claimed the rulers of the states as his colleagues and partners in the administration of the country. Lord Minto, perceiving an atmosphere of discontent, took the occasion to make a declaration of policy, during a visit to the Maharaja of Udaipur in Nov. 1909. He interpreted the proclamations of Queen Victoria and King Edward as inculcating a sympathetic, and therefore an elastic policy, and he laid stress on the fact that the foundation stone of the whole system must be the recognition of identity of interests between the Imperial Government and Durbars and the minimum of interference with the latter in their own affairs.

Lord Hardinge, pursuing the same policy, in 1913 and 1914 invited some of the princes to meet him in conference at Delhi to discuss a scheme for founding a central college at Delhi, and in 1914 he created a new post of political secretary to the Government of India, in order that closer attention might be devoted to relations with the states. The past fifteen years had proved an era of striking progress and development, and the rulers themselves, encouraged to play more important parts in the drama of Indian affairs, were becoming daily more advanced in their own administration, so that new methods of political treatment were required.

In Aug. 1914, on the outbreak of the War, the princes vied with each other in the offer of loyal service. In a telegram which stirred England the Viceroy reported that the rulers of the states in India, numbering nearly 700, had with one accord rallied to the defence of the Empire and offered their personal services and the resources of their states. Contingents of all arms were accepted from 12 states, besides a camel corps from Bikaner. A

INDIAN TEMPLES, TOWNS AND SOCIAL LIFE

1. Ruins of an ancient brick stupa near Benares. The upper part, in which a tree has grown, is covered with grass
2. The temple of Raja Chait Singh at Ramnagar near Benares, built about 1800 A.D. It includes stables for elephants and sacred cows
3. Group of temples on the river side at Ujjain, an ancient city of Central India situated on the Sipra
4. The grounds of the palace at Mysore during a ceremonial occasion
5. A Mohammedan girl wearing the usual head covering considered essential to modesty
6. Native shops in Darjeeling, a hill station of Bengal, British India
7. Caucasian types in India
8. A snake charmer in the city of Benares
9. A peasant girl wearing nose and ear rings
10. A market square in Darjeeling near the boundary between northern India and Tibet, where the hill people come on Sundays to buy and sell. Among the articles on display are tiger skins, rugs, jewelry, curkha knives, prayer-wheels, grains and tobacco
11. Bazaar in the market place before a temple at Jodhpur, Rajputana

hospital ship was given by various states at the instance of the Maharaja of Gwalior, and as the War progressed there were many fresh evidences of the spirit of loyalty animating the princes and their peoples. The support afforded by the Durbars in the matter of raising recruits was of particular value.

Minorities and Successions.—In 1916 Lord Chelmsford, in spite of war preoccupations, decided to invite the princes to another conference. In his opening speech he laid stress on the magnificent assistance rendered by the states. The most important of the subjects discussed at the conference related to the form of administration to be adopted in a state during a minority. This thorny subject, after full discussion at the conference, was made the text of a declaration in Aug. 1917 laying down the principles for the conduct of minority administrations. In it the Government of India asserted their rôle as trustees and custodians of the rights, interests and traditions of a state during a minority, but admitted that the special conditions of each state required special treatment, and promised to attach due weight to requests by individual ruling princes or chiefs regarding any principles which they might wish to be adopted in the case of their own states or families, while reserving to themselves freedom of action in dealing with such requests. Seventeen general principles were laid down for observance during minority administrations. The pronouncement was welcomed as an event hardly second in constitutional importance to the *sanads* of adoption granted by Lord Canning. The next conference, held in 1917, saw the decision of another very important question, viz.: the form of recognition by Government of successions in the states. Lord Chelmsford announced that in the case of the succession of a direct natural heir recognition on the part of a paramount power was purely formal, and that the obligation on the part of the new ruler to obtain it in no way impaired his inherent right to succeed.

The Chamber of Princes.—His Highness the Maharaja of Bikaner, who took the lead in this conference, expressed the hope of the princes that before the British Government made a decision on the subject of political reforms to be introduced in British India the ruling princes would also be consulted, and a constitutional chamber established to safeguard their interests. In Dec. 1919 the King issued a royal proclamation signifying his assent to the establishment of a chamber of princes, which was eventually inaugurated by the Duke of Connaught in Feb. 1921. In the proclamation then read, the following occurs:—

"In my former proclamation I repeated the assurance, given on many occasions by my Royal predecessors and myself, of my determination ever to maintain unimpaired the privileges, rights and dignities of the princes of India. The princes may rest assured that this pledge remains inviolate and inviolable. I now authorise my Viceroy to publish the terms of the constitution of the new chamber. My Viceroy will take its counsel freely in matters relating to the territories of the Indian States generally, and in matters that affect those territories jointly with British India, or with the rest of my Empire. It will have no concern with the internal affairs of individual states or their rulers or with the relations of individual states to my Government, while the existing rights of the states and their freedom of action will be in no way prejudiced or impaired."

His Royal Highness also conveyed to the princes a special message of thanks from His Majesty in public acknowledgment of their splendid record of achievement during the War. He alluded to the fact that H.H. of Bikaner had taken part in the Peace Conference and had signed the Treaty of Versailles, while H.H. the Maharaja of Nawanganar had attended the League of Nations Assembly at Geneva. H.H. the Maharaja of Bikaner was appointed to be the first chancellor of the chamber (Narendra Mandal), and was re-elected to the office each year until 1926 when he was succeeded by H.H. the Maharaja of Patiala.

The Salute states in the Punjab Province were taken into direct relation with the Government of India in Nov. 1921, through the appointment of an agent to the Governor-General. A similar arrangement was made in 1923 for the five states in the Madras Presidency, and in 1924 for the Bombay states of Kāthiāwār, together with Cutch and Palanpur, while the Bom-

bay Political Department was combined with that of the Government of India. In 1921 the Gwalior state was separated from the Central India Agency and brought into contact with the central Government through a single intermediary officer, while in Rājputāna the states of Bikaner, Sirohi and Jhālāwār were at different times placed in direct relations with the agent to the Governor-General instead of through a subordinate political agent. At the meeting of the chamber in the autumn of 1921, Lord Reading announced that for the future, except at installations and investitures, where local custom would continue to be followed, the King had been pleased to dispense with the presentation of nazars at ceremonial visits or receptions, either to himself or to the members of his family or to any of his officers to whom it had hitherto been customary to present them.

Constitutional Development.—While the paramount power has parted with none of its prerogatives, the evolutionary process has gradually led to a certain breaking down of the isolation of the states among themselves, the strengthening of their position and the advancement of the dignity of the princes. They not only gained, in the chamber, means for expression of their collective needs and opportunity for influencing the development of political doctrine, but they were admitted, as joint representatives of India, to the innermost councils of the Empire. In a few advanced states, legislative bodies have been constituted bearing some analogy to those in British India, Mysore being a prominent example, while in others the rulers have devised means for the people to voice their grievances and aspirations more easily through consultative councils. Thus the processes at work in British India are insensibly influencing the States and tending to break down their conservative traditions. At the same time the princes cannot but regard with interest the constitutional changes beyond their borders, and the possibility that they may ultimately be brought into relations with a democratic Indian Government in place of their present personal association with the Viceroy and his officers. This prospect has not been wholly absent from their motives in pressing for an enquiry into a number of questions of "political practice," which they claim to be derogations from their status as treaty powers. A committee appointed by the Government of India to make such an enquiry has been at work in 1928, and the princes sent a strong delegation to England, for the purpose of presenting their claims, as well as of interesting and instructing public opinion on a technical and little understood aspect of India's constitutional problems.

BIBLIOGRAPHY.—In contrast with the former scarcity of good books on India, they now abound; and the following is necessarily an arbitrary selection from the newer works. The standard all-round text-book is *The Imperial Gazetteer of India*, vol. 1 to 4. Add to this the Statistical Abstract of British India from 1914-15 to 1925-26 (Cmd. 3046 of 1928); and the reports to Parliament on the Moral and Material Progress of India, now published as *India* in 1918, etc., up to 1926-27 written by Prof. Rushbrook Williams, and later by Mr. J. Coatman, and bringing a full narrative of current events up to date.

Historical: Sir Verney Lovett's *India* in the "Nations of To-day" series (1923) is the latest authoritative work. Sir V. Chirol's trilogy should be studied: *Indian Unrest* (1910); *India Old and New* (1921); and "India" in *The Modern World* series (1926).

Constitutional and Political: The key book is the Report on Indian Constitutional Reforms (Cmd. 9109 of 1918) by the late E. S. Montagu and Lord Chelmsford. With it read *Dyarchy* by L. Curtis (Oxford, 1920), which contains the text of the Selborne Committee and the Act of 1919. Other works are E. A. Horne, *The Political System of British India* (Oxford, 1922); Sir C. Ilbert, *The Government of India* (Oxford, 1922); Ilbert and Meston, *The New Constitution of India* (1923).

Problems of to-day: Sir Verney Lovett, *History of the Indian National Movement* (1920); Bishop Whitehead, *Indian Problems* (1924), and as studies in Indian psychology, Lord Ronaldshay's trilogy, *Lands of the Thunderbolt, India: a Bird's-eye View, and The Heart of Aryavaria*, published by Constable in 1923-24, respectively.

Economics and Finance: Dr. P. P. Pillai, *Economic Conditions in India* (1925); Gyan Chand, *Financial System of India* (1926).

(ME.)

DEFENCE

The defence of India, involving as it does the services of the British and Indian Armies and Navies, and the Royal Air Force, naturally falls into three sections, dealing respectively with mili-

tary, naval and air operations, and will be dealt with accordingly.

ARMY

Historically, the Indian army grew up in three distinct divisions, the Bengal, Madras and Bombay armies. This separation was the natural result of the original foundation of separate settlements and factories in India.

Bengal.—The English traders in Bengal were long restricted by the native princes to a military establishment of an ensign and 30 men; and this force may be taken as the germ of the Indian army. In 1695 native soldiers were first enlisted. In 1756 occurred the defence of Calcutta against Suraj-ud-Dowla, and the terrible tragedy of the Black Hole. The work of reconquest and punishment was carried out by an expedition from Madras, and in the little force with which Clive gained the great victory of Plassey (*q.v.*) the Bengal army was represented by a few hundred men only (the British 39th, now the Dorsetshire regiment, which was also present, was the first King's regiment sent to India, and bears the motto *Primus in Indis*); but from this date the military power of the Company rapidly increased and in 1763 the total forces amounted to 1,500 Europeans and 12 battalions of native infantry (11,500 men). In 1765 the whole force was organized in three brigades, each consisting of one company of artillery, one regiment of European infantry, one troop of native cavalry and seven battalions of sepoy. In 1766, on the reduction of some money allowances, a number of officers of the Bengal army agreed to resign their commissions simultaneously. This dangerous combination was promptly put down by Clive (*q.v.*), to whom the Bengal army may be said to owe its existence. The constant wars and extensions of dominion of the next 30 years led to further augmentations; the number of brigades and of European regiments was increased to six; and in 1794 the Bengal army numbered about 3,500 Europeans and 24,000 natives.

Madras.—The first armed force in the Madras presidency was the little garrison of Arcot on the Coromandel coast, consisting of 28 soldiers. In 1644 Fort St. George was built and garrisoned, and in 1653 Madras became a presidency. In 1745 the garrison of Fort St. George consisted of 200 Europeans, while a similar number, with the addition of 200 "Topasses" (descendants of the Portuguese), garrisoned Fort St. David. In 1748 the various independent companies on the Coromandel coast and other places were consolidated into the Madras European regiment. From this time the military history of the Madras army was full of incident, and it bore the principal part in Clive's victories of Arcot, Kavaripak and Plassey. In 1754 the 39th regiment of the Royal army was sent to Madras. In 1758 three others followed. In 1772 the Madras army numbered 3,000 European infantry and 16,000 natives, and in 1784 the number of native troops had risen to 34,000.

Bombay.—The island of Bombay formed part of the marriage portion received by Charles II. with the infant of Portugal, and in 1662 the Bombay regiment of Europeans was raised to defend it. In 1668 the island was granted to the Company, and the regiment at the same time transferred to them. In 1708 Bombay became a presidency, but it did not play so important a part as the others in the early extension of British power, and its forces were not so rapidly developed. It is said, however, to have been the first to discipline native troops, and Bombay sepoys were sent to Madras in 1747, and took part in the battle of Plassey in 1757. In 1772 the Bombay army consisted of 2,500 Europeans and 3,500 sepoys, but in 1794, in consequence of the struggles with the Mahratta power, the native troops had been increased to 24,000.

Consolidation of the Army.—In 1796 a general reorganization took place. Hitherto the officers in each presidency had been borne on general "lists," according to branches of the service. These lists were now broken up and cadres of regiments formed. The colonels and lieutenant-colonels remained on separate lists, while the divisional commands were distributed between the royal and Company's officers. Further augmentations took place, consequent on the great extension of British supremacy, and in 1808 the total force in India amounted to 24,500 Europeans and 154,

500 natives. The first half of the 19th century was filled with wars and annexations and the army was steadily increased. Horse artillery was formed, and the artillery in general greatly augmented. "Irregular cavalry" was raised in Bengal and Bombay, and recruited from a better class of troopers, who received high pay and found their own horses and equipment. "Local forces" were raised in various parts from time to time, the most important being the Punjab irregular force (raised after the annexation of the Punjab in 1849). Another kind of force, gradually formed, was that called "contingents"—troops raised by the protected native states. The strongest of these was that of Hyderabad, originally known as the Nizam's army.

The Army Before the Mutiny.—The officering and recruiting of the three armies were in all essentials similar. The officers were mainly supplied by the Company's military college at Addiscombe in Surrey (established in 1809), and by direct appointments. The Bengal infantry was mostly drawn from Oudh and the great Gangetic plains and composed chiefly of high-caste Hindus, a sixth being Mohammedans, while the cavalry were mainly Mohammedans, recruited from Rohilkhand and the Gangetic Doab. The only other elements in the army were four Gurkha regiments, enlisted from Nepal, and the local Punjab irregular force. The Madras army was chiefly recruited from that presidency, or the native states connected with it, and consisted of Mohammedans, Brahmans, and of the Mahratta, Tamil and Telugu peoples. The Bombay army was recruited from its own presidency, with some Hindustanis, but chiefly formed of Mahrattas and Mohammedans; the Bombay light cavalry mainly from Hindustan proper. Including the local and irregular troops (about 100,000 strong), the total strength amounted to 38,000 Europeans of all arms, with 276 field guns, and 348,000 native troops, with 248 field guns—truly a magnificent establishment, and, outwardly, worthy of the great empire which England had created for herself in the East, but inwardly unsound, and on the very verge of the great mutiny of 1857. An account of the events of 1857-58 will be found under INDIAN MUTINY.

The Reorganization.—After the catastrophe the reorganization of the military forces on different lines was of course unavoidable. Fortunately, the armies of Madras and Bombay had been almost wholly untouched by the spirit of disaffection, and in the darkest days the Sikhs, though formerly enemies of the British, had not only remained faithful to them, but had rendered them powerful assistance.

On Sept. 1, 1858, the East India Company ceased to rule, and Her Majesty's government took up the reins of power. The local European army was abolished, and its *personnel* amalgamated with the royal army. The artillery became wholly British, with the exception of a few native mountain batteries. The total strength of the British troops, all of the royal army, was largely increased, while that of the native troops was largely diminished. Three distinct native armies—those of Bengal, Madras and Bombay—were still maintained. The reduced Indian armies consisted of cavalry and infantry only, with a very few artillery, distributed as follows:—

	Battalions Infantry	Regiments Cavalry
Bengal	49	19
Madras	40	4
Bombay	30	7
Punjab Force	12	6
Total	131	36

The Punjab force continued under the Punjab government. In addition, the Hyderabad contingent and local forces in Central India were retained under the government of India. After all the arrangements had been completed the army of India consisted of 62,000 British and 125,000 native troops.

The college at Addiscombe was closed in 1860, and the direct appointment of British officers to the Indian local forces ceased in 1861. In that year a staff corps was formed in each presidency "to supply a body of officers for service in India." The corps was at first recruited partly from officers of the Company's service and partly from the royal army, holding staff appoint-

ments (the new regimental employment being considered as staff duty) and all kinds of political and civil posts. The only English warrant and non-commissioned officers now to be employed in the native army were to be those of the Royal Engineers with the sappers and miners. In 1863 the system prevailing in the Punjab Frontier Force was applied to the whole army, each regiment and battalion having seven British officers attached to it for command and administrative duties, the immediate command of troops and companies being left to the native officers. Thus was the system reverted to, which was initiated by Clive, of a few British officers only being attached to each corps for the higher regimental duties of command and control.

A new spirit was breathed into the army. The supremacy of the commandant was the main principle. He was less hampered by the unbending regulations enjoined upon the old regular regiments, had greater powers, greater freedom of action, and was supported in the full exercise of his authority. The system made the officers. Many important changes took place between 1885 and 1904. Seven Madras infantry regiments were converted into regiments for service in Burma, composed of Gurkhas and hardy races from northern India; six Bengal and Bombay regiments were similarly converted into regiments of Punjabis, Pathans and Gurkhas; a system of linked battalions was introduced with the formation of regimental centres for mobilization; and reserves for infantry and mountain artillery were formed. The number of British officers with each regiment was increased to nine, and the battalions converted into four double-company commands of 250 men each, under a British commander, who should be responsible to the commandant for their training and efficiency, the command of the companies being left to the native officers. This system admitted of closer individual attention to training, and distributed among the senior British regimental officers effective responsibility of a personal kind.

An addition (at the imperial expense) of five battalions of Sikhs, Punjabi Mohammedans, Jats and hillmen in northern India was made in 1900, as the result of India being called upon to furnish garrisons for Mauritius and other stations overseas. The unification of the triplicate army departments in the different presidential armies was completed in 1891, all being brought directly under the supreme government; and the three separate staff corps of Bengal, Madras and Bombay were fused into one in 1891 as the Indian Staff Corps. The term "Indian Staff Corps" was in turn replaced by that of "Indian Army" in 1903. These measures prepared the way for the new system of army organization which placed the whole army of India under the governor-general and the commander-in-chief in India.

The Indian Defence Problem.—Before following the further development of the army in India, it is desirable to review the military problem as it appeared after the Boer War, when the Empire was taking stock of its military systems in the light of the experience there gained, and by the lessons of the Russo-Japanese War. Up till the days of the Mutiny in 1857 the armies of India were largely organized and located to dominate the powerful forces of the native states within India or on her borders. The fierce conflicts with the Sikhs and the annexation of the Punjab brought this period in some sort to a close, though in 1857 the troops of several of the states also mutinied against their own rulers and joined in that struggle. Between that period and the Boer War Britain had been at war with Burma and Afghanistan. The policy with regard to the latter country has always aimed at a strong, friendly, independent state, and for close on a hundred years the gradual absorption of the Central Asian Khanates by Russia and avowed threats toward India had made Britain very sensitive as regards the integrity of Afghanistan. Since 1881 the protection of Afghanistan against Russian aggression had been the keynote of the military policy as the major operation to be faced. At the same time there were and are other responsibilities. In the Far East, China, especially in time of disturbance, might be a very genuine and a very serious problem on the trade routes that run between China and Burma. On the Northern frontier, Nepal, which had overrun the submontane tract of India, the Himalaya, early in the nineteenth century, and might want to do

so again, could not be neglected. On the north-west frontier, the thousand miles of independent hill tribes between the administered British province and the Afghan boundary had presented a military problem ever since 1849, a problem, however, less costly than an annexation and pacification of the hills in which they lived. Since the World War, when modern rifles and ammunition were scattered over the battlefields of the East, the tribes have obtained possession of large quantities of modern arms and can easily number over 100,000 combatants. Added to these possible dangers, there has always been present the fear of internal disturbance, in a country of over 300,000,000 people of antagonistic races and religions, while the possibility of a repetition of 1857 could not be entirely disregarded.

Lord Kitchener's Reorganization.—Until the days of the Boer War, there had been no attempt to frame a principle of organization of the forces throughout the empire, or to evolve a scheme whereby all these forces should pass from a peace to a war footing. The lessons of that war produced a more definite train of thought. The decision was arrived at that the division should be the British war unit, and that it was desirable that each division and brigade should be trained together in peace by the men who would lead them in war. While the army in the United Kingdom was in process of reorganization, Lord Kitchener was sent to India to bring the army there on to modern lines, and more especially to prepare it for its major rôle, the defence of Afghanistan against Russian aggression. Lord Kitchener found that while there were four commands, the line was still numbered as three distinct presidential armies, and that there were numerous smaller forces which also had separate numerals. For instance, at least eight infantry battalions were numbered "1." Further there were many units formed of material which, from years of peaceful living, had lost their martial characteristics. The divisional organization in peace time did not exist and there was no definite allotment of troops to field army and garrison units, while it was impossible to collect units under the brigadiers who would train them, in view of the way in which the cantonments had grown up in pursuance of requirements which no longer existed.

Eventually, after much consideration, the following main reforms were inaugurated. The whole army was renumbered in one series; the Punjab Frontier Force, the Hyderabad contingent, the local regiments in Baluchistan and other corps hitherto deemed local were brought into one roster and made available for general service. The four commands were abolished and ten divisional areas were introduced (including Burma). Of these, at least seven were to contain a field army division of which the first five were to be complete in all essentials and the remainder maintained in a lesser state of preparation. The divisional area was to be the administrative unit, and, in addition to the field army division, might contain one or more cavalry brigades and a number of units, including the Volunteers, allotted to the maintenance of internal order, and the defence of arsenals and stores. Two commands, Northern and Southern, were formed, as inspectory rather than administrative organizations. In addition, certain independent brigades were created directly under Command Headquarters, chiefly the three areas on the frontier between the Khyber and the Gomal passes. The class composition of the battalions and cavalry regiments was exhaustively studied, companies and squadrons and, in certain cases, whole corps, being filled more definitely than heretofore by the martial classes and races so as to produce a healthy rivalry, and to supplement each other's qualities, while the less warlike races were largely eliminated, and new classes of fighting value that had hitherto been neglected were sought for. In this connection it cannot be too widely understood that in the immense population of India the number of men of martial proclivities and even personal courage is a very small proportion of the whole (for instance the entire Sikh community, men, women and children, barely number three million), and the great mass of the people, educated and otherwise, are quite devoid of any martial potentiality. The scientific grouping by race and creed which now ensued produced an army far superior in fighting value to anything that had existed before, and enabled the Indian Army to take so notable a part in the World War.

The great factor, however, which militated against the military efficiency of the Indian Army was the administrative system, inherited from the Moguls, suited to their period and to the warfare of the earlier days of the Company, which had broken down absolutely in the First and Second Afghan Wars, but which even in Kitchener's time was too economical in peace to be abolished. Under this system the native army provided its own food, horses, clothing and much of its equipment regimentally on a contract basis, and this meant that the administrative services to supply food, transport, remount, clothing, and equipment other than fighting equipment did not exist in peace in India save for the European troops, and could not be efficiently found in war. Kitchener, while doing what he could to improve matters, found that the cost was too prohibitive, and it was not till the breakdown of the Indian administrative services in the field during the World War that it was possible to put the supply, remount and ordnance services on the same footing as all other armies, and for the army to draw all its supplies through departmental army sources. Until this was done India had neither reserves of equipment nor personnel to deal with the war requirements. This essential measure of efficiency has, however, greatly increased the cost of the army.

The War Ministry.—Kitchener's administration will be most remembered by the controversy as regards the war minister, or, in Indian terms, the military member of the Governor-General's council. Hitherto, the military member, though a distinguished soldier, was in the position towards the commander-in-chief of secretary of State for war. Kitchener urged that, in a country like India where war problems were always immediate, a civilian minister was not a suitable one, while a military member must always tend to clash with the commander-in-chief, who should be the sole military adviser of Government. In spite of strong opposition from Lord Curzon, the Viceroy, Kitchener's view prevailed, and the commander-in-chief with a small secretariat on the civil side, was to be also secretary of State for war or, as it was now to be termed, "army member" of the Governor-General's council. A further measure of efficiency, which was of immense value in the World War, was the starting in India of gun, rifle and cordite factories on a large scale, so that India should be more independent of Europe for munitions than she had been since the introduction of rifled and breechloading weapons. The organization and training of the staff on a more thorough system was also undertaken in Kitchener's time, by the establishment of a staff college in India, the institution in England not being large enough for both armies. A few years before the World War, India followed the example of Great Britain in establishing a general staff on modern lines.

The World War.—When the World War broke out, India was able to despatch forces to Mesopotamia, primarily to protect the oil fields, to East Africa, and to Egypt to hold the Canal. The best force, however, was almost immediately sent on to France and more troops sent to Egypt in their stead, while India denuded herself to the point of danger of her war reserves, a course Britain's alliance with Russia alone made possible. The system of administrative services referred to above, militated for some time against the full efficiency of her forces, but these matters were put on a modern basis as time went on. The military contribution by India to the World War, of troops who in their real aspect were mercenary is a remarkable tribute to the general loyalty and affection of the martial classes of India inspired by the Crown. Eventually the Indian forces were concentrated in the Mesopotamia and Palestine theatres in terrain more suited to them than that of France.

Hardly was the war over when, in 1919, immediately after the rebellion in the Punjab, the Amir of Afghanistan invaded India, when the force was in the midst of demobilizing, and the best part of the Indian army still overseas. Driving back the Afghans after some hard fighting, the army then found itself involved in some three years' frontier operations, the direct result of the upset of the tribes on the frontier by the Afghan invasion. *Pari passu* with these prolonged operations, the Indian army needed remodeling in the light of the experience of the World War and the post-war conditions. The principal changes introduced were the aboli-

tion of practically half the Indian cavalry by combining regiments, the disbanding of all the Carnatic battalions and the reduction by several thousand men of the British army to be maintained in the country. In actual organization, the army was divided into four commands, in lieu of the two inspectory commands of the Kitchener organization, with divisional areas somewhat readjusted. The troops holding the frontier were to be called the covering force, and were to be fully mobilized and strong enough to allow of the army behind mobilizing at leisure. In addition, five divisions, those of Peshawur, Rawal Pindi, Quetta, Mhow and Meerut, were to be considered field army formations. Motor transport companies were introduced and a large repair works opened at Rawal Pindi. The administrative services were to remain as constituted during the war, on the same lines as the British army, and the old, cheap but ineffective Mogul system was not returned to. A radical change in the grouping of the infantry was introduced as the result of the experience of the war.

All battalions were grouped into regiments of several service battalions and one depot or "training" battalion, and the new regiments numbered entirely fresh with due regard to the dates of the original raisings of the various corps. The class composition of many corps was also rearranged to allow for simpler reinforcement in war time. In the new organization it was necessary to absorb the famous corps of Guides into the line of the cavalry and infantry. The Gurkha two-battalion regiments, ten in number, alone retained their pre-war organization. The volunteer force of pre-war days, which during the War had been called the defence force, was now reorganized and termed the auxiliary force, and deemed to be a second line to the British troops in India, while a new Indian territorial force was inaugurated, on much the same lines as the territorial army in Great Britain.

A considered policy was also adopted in the last years of the War and continued after, of admitting Indian gentlemen to commissions with the same status as British officers, a number of young men being put through Sandhurst each year, and schools being started in India to train them in their younger days. It was also decided to select certain corps in which the officer cadre should, as an experiment, be in due course completely Indianized. The reductions and regrouping brought the number of European units in India from 9 to 6 cavalry regiments and from 51 to 45 battalions and the Indian units from 39 to 21 cavalry regiments, and from 129 to 140 battalions, which include 21 training battalions for each of the regiments. This number varies slightly according with the overseas obligations which the Government of India may have undertaken. The strength of the artillery consists of 9 horse artillery batteries of which four are brigaded, 11 brigades of field artillery totalling 44 batteries, 3 heavy brigades of 11 batteries and 6 mountain artillery brigades of 24 batteries of which 12 are Indian. The total strength of the reorganized army in India which varies slightly from year to year is some 204,000 men of whom two-thirds are Indian and one-third British.¹

The Armies of the Native States.—A description of the Indian army would not be complete without a reference to the armies of the Native States of India. In 1885 these forces were numerous, badly disciplined, ill-armed and yet costly. The Penjdeh incident on the Afghan-Russo frontier in 1885, and the subsequent imminence of war with Russia, produced loyal offers by the rulers of many states to contribute in men or money to the defence of India. Eventually was evolved a policy of each state preparing a certain portion of its troops for the service of the Indian Empire in war. They were termed "Imperial Service Troops," and were armed by the British Government while British officers superintended their training. In their place a considerable portion of the older and badly organized state troops were disbanded. From 1890 to 1914 these troops took part, by the offer of the rulers, in many of the campaigns on the frontier, China, etc., in which the Indian army took part, and during the World War served far afield in many theatres of war. After the war, the rulers undertook to place all their troops, if need be, at the service of the empire, and the term "Imperial Service" was

¹The Army in India and its Evolution, Government Press, Calcutta.

abandoned for the better trained portion, and the term "State Troops" applied to the whole. Several of the Princes themselves accompanied their troops into the field. The State Troops comprised infantry, cavalry, engineers and transport, and in Kashmir, which alone of the States of India was on the outer border and marched with Russia, two mountain batteries existed. Under the post-war organization some artillery is being added to the State forces in the interior.

Mechanization.—Mention is necessary of the mechanization desirable and possible in India. At present, apart from other factors, it is hampered by the low state of mechanization in civil life, and the absence of manufacturing or repairing firms of any size. For the repair of its own vehicles the Government of India have had to build large works, and are not able to rely on aid from civil firms. So far as the tactical requirements go, the heavy artillery and a proportion of the field artillery can undoubtedly be mechanized and some progress has been made. Where carts were expected to take supplies in the past, there lorries can go with advantage, while the coming of the lorry has immensely simplified transport problems so far as the main lines of movement towards Central Asia are concerned. The mechanizing of the mounted troops is a more complex problem. In India much of the cavalry exists for the *prevention* rather than the *suppression* of disturbance. The sight of lancers streaming across country must always be far more impressive than the presence of a few tanks and armoured cars, however much more destructive these may be when actual rebellion has broken out. (G. MA.)

Navy.—For three centuries a naval service, under various designations has been maintained in Indian waters. The East India Company, under their charter, maintained an armed naval force and in 1829 the Company founded an Indian Navy. After the Mutiny this service was abolished for reasons of economy and an Indian Marine Service was formed which developed, in 1892, into the Royal Indian Marine. In 1914 this force consisted of six armed transports manned by British officers and native crews. During the war the ships were employed in patrolling the Red Sea and the Persian Gulf, and the Royal Indian Marine took charge of the inland water transport in Mesopotamia until the end of 1916. The Indian Government besides maintaining the Royal Indian Marine, pays annually a sum of £100,000 towards the upkeep of the British East Indies Squadron, which has its base at Trincomalee.

Reforms in the internal government of India have engendered a desire that the Indian Empire should have a Navy of her own: "such force, raised by the Governor in Council to be used for the purpose of the Indian Empire alone, except if a state of emergency be declared, when the Governor may place all or any of the ships at the disposal of the British Admiralty." The force is to be commanded by a British Flag Officer and one third of the vacancies for officers are to be held open to Indians. The formation of the new navy was delayed, early in 1927, by the rejection (by one vote) by the Indian Parliament of necessary legislation dealing with naval discipline. In this situation the Indian Government proceeded with the reorganization of the Royal Indian Marine, with a view to its conversion, in due course into the Royal Indian Navy. At the end of 1928 a British Rear-Admiral was appointed to command the new force and the training of a few Indian officers was commenced in England. (S. T. H. W.)

The Air Force.—The Royal Air Force in India is under the control of the Air Vice-Marshal, who is under the supreme control of the Commander-in-Chief. Originally it comprised six squadrons organized in three wings of two squadrons each and its establishment was 218 officers and 1,757 British and 138 Indian other ranks. The Aircraft Depot and the various Aircraft Parks are directly under R.A.F. Headquarters in India.

The growing need for aerial defence in various parts of India resulted in claims being made by the Government of India for an extension of the existing equipment of the air stations. The use of the machines in reconnaissance, and the possibilities of their use in actual warfare or frontier risings, was freely discussed and the advantages of this arm in a country of long distances were clearly recognized. Those squadrons already in use were

a charge on the Indian Government, and, after lengthy discussion, it was decided in May 1928 to make application for two other squadrons, and two new units, taken from the Wessex or Bombing Area of the Home Defence Force, were sent to India at the end of December, 1928. These were No. 11 Squadron, formerly stationed at Netheravon, and No. 39 Squadron, which was stationed at Bircham Newton, and they were equipped in England before departure with Hawker Horsley and D.H. 9a aircraft engines. In India, however, they were to be re-equipped with Westland Wapite general purpose aircraft engines. No. 11 Squadron has 11 officer and six airman pilots and No. 39 has 13 officer and seven airman pilots. This squadron was for some years associated with the massed bombing formations at the annual R.A.F. display at Hendon. The destination of the units was Risalpur on the North-West Frontier.

The splendid work done during the Afghan troubles of 1928-29 by the R.A.F., in rescuing British subjects and foreigners of every nationality from Kabul and transporting them to Peshawar was the subject of favourable comment throughout all Europe. King Amanullah himself was thus transported after his formal abdication. (X.)

ECONOMICS

Resources.—Agriculture is, as it has always been, the dominant feature in the economics of India. According to the 1921 census, close to three-fourths of the total population derive their being from occupations connected with the land, while no other single industry supports as many as 3 per cent of the inhabitants. And the fertility of the land, except where it is protected by irrigation, largely depends on the adequacy and timeliness of the monsoon rains. Should they fail, vast areas remain unsown or yield no harvest: masses of people, chiefly agricultural labourers and petty cultivators, are thrown out of employment; and their inability to get food, or to buy it when as now it is brought to their doors, constitutes that heart-rending calamity, an Indian famine.

The second powerful force which affects the economic situation in India is the constant demand of the outer world for her raw produce, coupled with her own industrial weakness in converting that produce into manufactured articles. From earliest times India was noted for her spices, her precious stones and her delicate textiles: in return she imported gold and silver in untold quantities and absorbed them. Spices are no longer a necessity in western diet; the diamond-mines of Golconda have been worked out; and the famous Cashmeres and muslins have been ousted, like cottage industries everywhere, by loom-made substitutes. To-day what the outer world clamours for is the surplus wheat, rice, cotton, jute, oilseeds and hides: and what it gives India in exchange is manufactured cotton (piece-goods) and yarn, metals and machinery, sugar and oil.

Agriculture.—The cultivation of the soil occupies the Indian people in a sense which it is difficult for the foreigner to realize, and which cannot be adequately expressed in figures. The village community contains many other members besides the cultivator: but they all exist for his benefit, and all alike are directly maintained from the produce of the village fields. The operations of rural life are familiar to every class. Everywhere, the same untiring labour is found, but inherited experience had taught the cultivators to adapt their simple methods to different conditions. Irrigation, apart from the great network of government canals, is practised wherever possible from wells of all types and depths, from tanks and evanescent streamlets. Manure is applied to the more valuable crops wherever it is available, although the land as a rule is starved by the much more insistent demand for manure as fuel. The rotation of crops is an ideal that is widely recognized, but poverty, as at every other turn, makes the use of periodic fallows unattainable. On the other hand, the regularity of the seasons allows two, and on highly manured soils even three, harvests in the year, though comparatively rarely on the same fields; and there is much natural fertility. For inexhaustible productiveness, and for retentiveness of moisture in a dry year, no soil could surpass the "black cotton soil"; but at the other end

of the scale vast areas of the driest sandy land are coaxed to yield a scanty harvest of poor millets and thin pulses. An elaborate report on the whole subject of Indian agriculture was issued in the autumn of 1928 by the Linlithgow Commission.

Departments of Agriculture.—Despite the innate conservatism of the peasantry, and in the face of a very inadequate provision of staff and funds, the departments of Agriculture, which were organized early in the century, have achieved a variety of important results. In the fore-front of their work has been the introduction of improved varieties of plants. This involves, firstly, research in order to obtain from abroad, or evolve locally, the variety which will prove its superiority under Indian conditions; secondly, growing the improved variety in sufficient quantities to furnish the ryots with seed; thirdly, convincing ryots by means of demonstration farms, and otherwise, of the advantage offered; and, fourthly, in many cases, watching over the subsequent fate of the new variety to prevent it from being swamped by inter-mixture with others. The area sown in 1923-4 with improved varieties popularised in this way exceeded 5,000,000 ac., including over 2,000,000 ac. under wheat and rice, and even more under cotton. The Imperial Research Institute at Pusa has had remarkable success in its work with wheat, particularly in the introduction of types which are immune from rust; very valuable work has also been done on sugar at Coimbatore.

Irrigation.—In the age-long contest against the tyranny of a semi-tropical climate, irrigation has played the dominant part, not only as a preventive of scarcity due to drought, but as an everyday adjunct to the productivity of the soil. In 1925-26 the area actually sown (some of it more than once) in British India was 257 million acres, of which close on 48 millions were irrigated. About half the irrigated area is supplied from canals; the rest largely from wells and tanks. The canal system is one of the greatest achievements of the British government, and it is steadily extending. It embraces the great Ganges canals in northern India, with over 1,200 miles of main channels and 6,500 miles of distributaries; the vast network of the Punjab canals, and the elaborate Delta systems of Madras, besides extensive works in Sindh and Deccan. Some of these draw on rivers fed by the Himalayan snows: others are channels for inundation and thus of less assured permanency: others again, chiefly in Madras, are supplied by storage works. The substitution of a permanent supply for the uncertainties of an inundation supply is in the fore-front of the modern projects. Among these the greatest, and indeed one of the largest in the world, is the Sukkur barrage in Sindh. At the point where the combined five rivers of the Punjab enter Sindh through a narrow gorge, the flow will be stemmed by a barrage 4,725 ft. long between abutments. The inundation system of Sindh will be served, and a vast new area brought under irrigation, by seven canals which will take off from the barrage, and which will ultimately water close on 6 million acres, or considerably more than the whole cultivated area of Egypt.

Second only to the Sukkur scheme in magnitude is the Sutlej Valley project. It consists of four weirs, with ten main canals taking off from above them, and irrigating over 5 million acres in British and State territory which are now partly waste and partly served inadequately by inundation channels. Outside the Indus basin there is no scope for works of equal magnitude, but a great scheme has just been completed for the irrigation of Oudh, by canal fed from the Sarma river. This project had been under contemplation for 50 years, but was in abeyance because of the opposition of the Oudh landowners (talukdars). The area to be irrigated is estimated at 1,700,000 acres. In Madras even older schemes first planned by Sir A. T. Cotton, the great pioneer of scientific canal irrigation in India, have been revived, for great storage reservoirs in the Cauvery, Bhavani, Tangabhadra and Kistna rivers, and the Cauvery scheme is well advanced. Two great dams are being erected in the Deccan, one of which is said to be the largest mass of masonry in the world: and all over India smaller works are being planned. An irrigable area of 50 million acres is aimed at.

Crops.—Of the total cropped area in British India, fully one-third is occupied by rice, which is the dominant crop of the staple

food in Bengal, Bihar and Orissa, and in Burma, as well as parts of Madras and the United Provinces, the so-called Patna rice coming mainly from the latter. Burma however is the great exporter and Germany its chief customer. The total value of the rice export in 1925-26 was £30,000,000 sterling.

In area the next most important crops are the great variety of millets and pulses. The millets are probably the most prolific grain in the world, and the best adapted to the vicissitudes of a tropical climate, requiring practically no irrigation.

Grain is the predominant variety, and occupied over 10 million acres in the U.P. and Punjab alone: but lentils and the smaller pulses are more universal. They are not an export commodity.

Wheat was grown on 24 million acres, of which more than two-thirds was in the U.P. and Punjab. The canal colonies of the Punjab have turned northern India into one of the chief granaries of the British Empire: and the total export of wheat in a bumper year (1924-25) rose to 1,112,000 tons (value £14 millions), of which 68 per cent was taken by the United Kingdom.

Cotton.—The great cotton areas are Bombay and the Central Provinces: the total acreage being now over 18 millions.

The export of raw cotton in 1925-26 was close on 750,000 tons: but the figure for cotton twist and yarn has fallen grievously in recent years, mainly owing to the activity of Japan. Much is being done to improve the staple: and an Indian Cotton Committee has been established, which is financed by a small cess on the output. It has taken measures for the control of cotton gins and the transport of cotton, in order to prevent adulteration and the intermixture of inferior varieties. There is now more Indian cotton on the Liverpool market than before the war, and the difference in the price it realizes as compared with American has almost disappeared. The total crop of Indian (including the States) cotton has reached 6 million bales of 400 lbs., as compared with a pre-war quinquennial average of 4 million bales: Japan and China readily swallowing the excess.

Oilseeds, Sugar and Jute.—A crop of great importance and universally grown is the mixed group which yields oilseeds: for oil is an essential to the Indian toilet, to Indian cookery and as an illuminant. The chief varieties are ground-nuts, sesamum, rape or mustard, and linseed, which between them occupy nearly 13 million acres. The export has attained a value of £25,000,000, France being now the chief customer and Great Britain the second.

Barley, maize and fodder crops each cover more than 5 million acres: and the sugar cane accounts for roughly 3 million acres, nearly one half of which is in the United Provinces. It is an expensive crop, occupying the land for more than a year and exhausting it: but the yield is poor compared with that of other countries, and it has to be supplemented by heavy imports.

The world's supply of jute is derived almost wholly from Bengal.

Indigo.—Owing to the manufacture of synthetic indigo by German chemists the export trade in indigo, which was formerly the most important business carried on by European capital in India, has been almost entirely ruined. In the early years of the 19th century there were colonies of English planters in many districts of Bengal, and it was calculated that the planters of North Behar alone had a turnover of a million sterling. In 1895-1896 the area under indigo was 1,570,000 acres, and the value of the exports £3,569,700, while in 1925-26 the area had sunk to 133,000 acres, and the value of the exports to £42,000.

Tea.—The cultivation of tea in India has replaced indigo as the chief article for European capital, more particularly in Assam. The real tea (*Thea viridis*), a plant akin to the camellia, grows wild in Assam, being commonly found throughout the hilly tract between the valleys of the Brahmaputra and the Barak. There it sometimes attains the dimensions of a large tree; and from that, as well as from other indications, it has been plausibly inferred that Assam is the original home of the plant, which was thence introduced at a prehistoric date into China. The area under tea in 1885 was 283,925 acres and the yield 71,525,977 lb., while in 1925 the area had increased to 728,860 acres and the

yield to 363 million lbs., the export alone being worth over £20,000,000 sterling. The United Kingdom takes 88 per cent of the export and the home consumption is rapidly rising.

Coffee.—The cultivation of coffee is confined to southern India, though attempts have been made to introduce the plant both into Lower Burma and into the Eastern Bengal district of Chittagong. The coffee tract includes almost the whole of Coorg, the districts of Kadur and Hassan in Mysore, the Nilgiri hills, and the Wynaad. The cultivation has also extended to the Shevaroy hills in Salem district and to the Palni hills in Madura. Although local tradition dates its introduction two centuries back, coffee was not grown systematically until 1840. Since 1860 it has spread with great rapidity along the whole line of the Western Ghats, clearing away the primeval forest, and opening a new era of prosperity to the labouring classes. The export of coffee in 1905 was 360,000 cwt.; but mainly owing to the competition of Brazil, it has fallen considerably. The United Kingdom and France are the chief consumers. There is practically no local market for coffee in India.

Cinchona.—The cultivation of cinchona was introduced into India in the year 1860 under the auspices of government, owing to the efforts of Sir Clements Markham, and a stock of plants was prepared and distributed to planters in the Nilgiris and in Coorg. At the same time governmental plantations were established in the Nilgiri hills and at Darjeeling, and these have been continued up to the present time. A considerable amount of the bark from private plantations is bought by the government and treated at the government factories.

Garden Crops.—Vegetables occupy an important place in the Indian dietary and are grown everywhere. Besides the ordinary European species, which can mostly be grown in the cold season, the favourites are the egg-plant (brinjal), garlic, yams and a great variety of cucurbitaceous plants. Among cultivated fruits the commonest are the mango, plantain, guava, tamarind, jack, pomegranate, pineapple, papaw, custard-apple and several varieties of fig, melon, orange, lime and citron. The mangoes of Bombay, of Multan and of Malda in Bengal, and the oranges of Nagpur and the Kasi hills, enjoy a high reputation; while the guavas of Madras make an excellent preserve. Spices form another essential element in the Indian diet: turmeric and chillies are in universal use and are cultivated everywhere. Ginger, coriander, aniseed, black cummin and fenugreek come next in importance. Pepper is confined mostly to the Malaba Coast, and cardamoms are hardly less localized. *Pan*, however, or betel-leaf, is grown pretty generally: it is a difficult crop, tended by a special caste. The betel-nut or areca palm is found in the deltaic districts of Bengal and the highlands of northern India. Other palms include the coco-nut, which flourishes on the western coast of south India; the bastard date, which supplies the jaggery sugar of commerce and the intoxicating liquor known as *tari* or *toddy*; the palmyra, and the true date which grows only in Sind.

Co-operation.—To the improvement of Indian agriculture few obstacles are so grave as the chronic indebtedness of the peasantry. Legislation to combat this by restricting the alienation of rights in land has long been active: but the most effective remedy yet devised is undoubtedly the establishment of rural credit banks on the Raiffeisen plan. It was initiated by an Act of 1904, when registrars of co-operative societies were appointed for the different provinces, to draft model rules, register, inspect and audit the accounts of co-operative banks, and also to carry on propaganda and education in co-operative principles. In 1912 an amending Act was passed, as the result of eight years' experience; and also to extend the official encouragement to co-operation in other fields. The number of registered societies increased from 5,432 in 1911 to 80,182 in 1926; the membership from 308,000 to 3,287,000; the capital employed from Rs.227 lakhs to Rs.57 crores (about £43,000,000). The great majority of the societies are village banks; but there are a large number of "Central Banks" situated in towns, which gather in deposits, supply funds to the rural banks in their neighbourhood, and act as links between them. There are also "Apex" banks, for most of the provinces, Assam and Mysore.

Cattle.—Throughout the whole of India, except in Sind and the western districts of the Punjab, horned cattle are the only beasts used for ploughing. The well-known humped species of cattle predominates everywhere, being divided into many varieties. The last livestock census in 1924-25 returned 150 million cattle in British India: but, owing partly to unfavourable conditions of climate and soil, partly to the insufficiency of grazing ground, and partly to the want of selection in breeding, the general condition of the cattle is miserably poor. There are, however, some fine breeds in existence. In Mysore the *amrit mahal*, a breed said to have been introduced by Hyder Ali for military purposes, is still kept up by the state. In the Madras districts of Nellore and Kurnool the indigenous breed has been greatly improved, and in the Central Provinces there is a peculiar breed of trotting bullocks which is in great demand for wheeled carriages. The large and handsome oxen of Gujarat in Bombay and of Hariana in the Punjab are excellently adapted for drawing heavy loads in a sandy soil. Cattle-breeding farms have been set up by the government in different parts of the country; and invaluable work is being done by the Veterinary Service in the discovery and use of a serum prophylactic against the devastations of rinderpest. The worst cattle are to be found always in the deltaic tracts, but there their place is to a large extent taken by buffaloes. These last are more hardy than ordinary cattle; their character is maintained by crossing the cows with wild bulls, and their milk yields the best *ghi* or clarified butter. Along the valley of the Indus, and in the sandy desert which stretches into Rajputana, camels supersede cattle for agricultural operations. The breed of horses is little better than that of milch-kine. In Bengal and in Madras, it may be broadly said that horses are not bred. But horses are still required for the Indian cavalry and the police; and in order to maintain the supply of remounts a civil veterinary department was founded in 1892. Horse-breeding is carried on chiefly in the Punjab, the United Provinces, and Baluchistan, and government keep a number of stallions in the various provinces. Formerly Norfolk trotters held the first place in point of number, but their place has been taken in recent years by English thoroughbreds, Arabs, and especially Australians. For the supply of ordnance, baggage, and transport mules a large number of donkey stallions have been imported by the government.

Forests.—Up to 1850 the destruction of forests by timber-cutters, by charcoal-burners, and above all by shifting cultivation, was allowed to go on everywhere unchecked. But as the pressure of population on the soil became more dense and the construction of railways increased the demand for fuel, the question of forest conservation forced itself into notice, while its importance also as affecting the general meteorology of a country was being learned from bitter experience in Europe. In 1864 Dr. Brandis was appointed inspector-general of forests to the government of India, and in the following year an act of the legislature was passed (No. VII. of 1865). In the interval that has since elapsed, sound principles of forest administration have been gradually extended. Indiscriminate timber cutting has been prohibited, the burning of the jungle by the hill tribes has been confined within bounds, large areas have been surveyed and demarcated, plantations have been laid out, and, generally, forest conservation has become a reality. In 1894 the government divided forests into four classes: forests the preservation of which is essential on climatic or physical grounds, forests which supply valuable timber for commercial purposes, minor forests, and pasture-lands. In the first class the special purpose of the forests, such as the protection of the plains from devastation by torrents and the conservation of the rainfall for the service of the great canals, must come before any smaller interests. The second class includes tracts of teak, *sal* or *deodar* timber, and the like, where private or village rights of user are few. In these forests, while every reasonable facility is afforded to the people concerned for the satisfaction of their needs, restrictions are imposed, and the system of shifting cultivation is only permitted, under due regulation, where forest tribes depend on it for their sustenance. In the third place, there are minor forests, which produce inferior

or smaller timber. These are managed mainly in the interests of the surrounding population, and supply grazing or fuel to them at moderate rates. The fourth class includes pastures and grazing grounds. In these even more than in the third class the interests of the local community stand first. The state forests, which are under the control of the forest department, amount to about 227,500 sq.m., or more than one-fifth of the total area of British India, varying from 68% in Burma to 5% in the United Provinces.

Timbers.—A large part of the reserved forests, where the control of the forest department is most complete, consists of valuable timber, in which the first place is held by teak, found at its best in Burma, on the south-west coast of India, and inland from the Ghats as far as the middle of the Central Provinces. Here it meets the *sal*, which, however, is more especially found in the sub-Himalayan tracts of the United Provinces and Eastern Bengal and Assam. In the Himalayas themselves the *deodar* and other conifers form the bulk of the timber while in the lower ranges, such as the Khasi hills in Assam, and those of Burma, various pines are prominent. In the north-east of Assam and in the north of Upper Burma the *Ficus elastica*, a species of India-rubber tree, is found. The sandal-wood flourishes all along the southern portion of the Ghats, especially about Mysore and Coorg; and in the same regions, as well as in Upper India, the blackwood occurs. A valuable tree, known as the padouk, is at present restricted almost entirely to the Andaman Islands, with a scattering in Lower Burma. There are many other timber trees that are in general demand in different parts of India. The annual yield of timber and fuel from the Indian forests is over 300 millions of cubic feet. About half of this quantity comes from the forests of Burma, where large amounts of teak and other woods are annually extracted, chiefly through the agency of private firms. Many by-products of the forests are now being exploited on commercial lines; and the great Forest Research Institute at Dehra Dun is busy on silvicultural work and wood technology.

Mineral Resources.—The chief underground wealth of India, apart from salt which will be discussed separately, is derived (in order of its present value) from coal, petroleum, manganese, gold, lead, silver, iron and copper; the first two being by far the most important.

Coal was first mined at Raniganj in 1820. It exists in varying quantity under a very extensive area, being found almost everywhere except in Bombay and Mysore. The finest coal, however, and the largest output by far come from the seams in Chota Nagpur and the adjoining districts of Bengal. There are also considerable mines in the Central Provinces and the contiguous State of Rewah and an important field in Hyderabad. The value of the total output is now in the neighbourhood of £10 million sterling, and there are 242 companies working in the industry.

The great oilfields of India are in Burma, which supplies 90% of the total output. The remainder comes from Assam and from new wells in the Punjab; and the total output is valued at something like £8 million.

A comparatively new industry is the extraction of manganese ore, which is found in large quantities in the Central Provinces, as well as in scattered parts of Madras, Bombay and elsewhere. The production in 1925-26 was 839,000 tons.

The mining of gold is practically confined to the Kolar gold fields in Mysore, the amounts obtained by sand-washing in scattered areas elsewhere being negligible. The mines are worked under leases from the Mysore government, which secure to the State a royalty of 5 per cent of the production.

Silver and lead have an output which has risen to 5 million ounces and 50,000 tons respectively. They come from mines in the Northern Shan States of Burma. There is also an inconceivable vein of silver in Mysore.

The centre of the iron deposits is in the State of Mayurbhanj and the adjacent tracts in Orissa. It is the contiguity of iron ore and coal that determined the site of the great Tata works at Jamshedpur in the midst of what was formerly a primitive jungle. Mica has long been obtained in Bihar, chiefly in the

Hazaribagh district, and there is a ruby-coloured variety which is held in great estimation. In Madras also a mica industry has grown up. Tin is found in the Tavoy and Mergui districts of Lower Burma, and was for many years worked in an unprogressive manner chiefly by Chinese labour, until the recent increase of the world demand led to improved methods. Copper ore is found in many tracts throughout India, plumbago in Madras, corundum in southern India, wolfram in Burma and chromite in Baluchistan.

Precious Stones.—Despite its legendary wealth, which is really due to the accumulations of ages, India cannot be said to be naturally rich in precious stones. Under the Mohammedan rule diamonds were a distinct source of state revenue; and the name of Golconda has passed into literature, but that city, once the Mussulman capital of the Deccan, was rather the home of diamond-cutters than the source of supply. At the present day the only place where the search for diamonds is pursued as a regular industry is the state of Panna in Bundelkhand. The stones are found by digging down through several strata of gravelly soil and washing the earth. Even there, however, the pursuit is unremunerative, and has failed to attract European capital. At the present day the only important industries are the rubies and jade of Burma. The former are worked by the Ruby Mines Company or by licensed miners under the company. Pearls are found off the southern coast of Madras, on the shores of Gujarat and in the Mergui archipelago.

MANUFACTURING INDUSTRIES

Cotton and Jute.—On the basis of the number of people who are employed hand-loom weaving is still by far the greatest of Indian non-agricultural industries. The census of 1921 found very nearly 2,000,000 hand-loom weavers at work, and the actual number was probably considerably greater. The Indian Industrial Commission (1916-18) discovered that the consumption of mill-spun yarn by hand-loom weavers increased by about 30% in the two decades before the war, which would more than compensate for the diminution in the output of hand-spun yarn. But from 1922 onwards, in the fierce and very equal competition which so ensues between Indian and Japanese mills, it is the hand-loom weavers who have suffered most. In some districts after a struggle to live on less than subsistence earnings, they have been compelled to abandon their hereditary calling; in others, where the level of skill and enterprise is higher, they have given up cotton weaving for silk, or textures with gold or silver thread interwoven. The industry as a whole shows a surprising degree of vitality, fly-shuttles, which increase a weaver's output from 20 to 100%, have been adopted widely, and so also have simple machines for winding and warping, owned and used co-operatively.

Out of some 1,500,000 workers in factories of all sorts, about 330,000 are employed in cotton-mills, and some 140,000 in cotton gins and presses. This industry has had very considerable vicissitudes, but taking bad years with good, it has been prosperous and progressive. Before the War Indian mills supplied just under 30% of the total Indian consumption of mill-woven cloth: their share has now risen to 52%; while the share of the United Kingdom has fallen from 68.5% to 42.5. On the other hand, Indian mills have lost in China their chief foreign market. The first cotton mill in India was opened in 1851, and the industry received a powerful stimulus during the American Civil War. The staple, however, is short; and until the cultivation of better varieties is more general, no competition will be possible with cottons of the American type, and trade must be confined to the home and far eastern markets.

The manufacture of jute employs about 350,000 hands, and in this field the supremacy of Bengal is more firmly established than ever. Nearly two-thirds of the jute crop is worked up in the Bengal mills; so that Bengal now produces about twice as great a bulk of jute manufactured goods (gunny bags, hessian cloth, cordings, etc.) as all the rest of the world.

Silk.—The silk industry in India has experienced many vicissitudes. Under the East India Company large quantities of mulberry silk were produced chiefly in Bengal, and exported

to Europe; and Malda, Murshidabad, and other places in that province have long been famous for their silk manufactures. Other kinds of silk are native to certain parts of India, but the chief of the wild silks is the tussore silk, which is found in the jungles nearly throughout India. Large quantities of comparatively coarse silk are made from silk so produced. The most hopeful ground, however, for the industry is Kashmir, where Sir Thomas Wardle reported that the silk was of as high a quality as from any part of the world. The most important seat of the silk-weaving industry is Bengal, but there are few parts of India where some silk fabrics are not woven.

Other Manufactures.—The demand of the Indian population for woollen fabrics is very small in comparison with that for cotton, and although the manufacture of blankets is carried on in many parts of India, the chief part of the indigenous woollen industry was originally concerned with shawls. Kashmir shawls were at one time famous, but the industry is practically extinct. The chief seat of the woollen industry now is the Punjab, where a considerable number of weavers, thrown out of work by the decline of the shawl industry, have taken to carpet-making. The chief centre of this industry is Amritsar. The output of the woollen mills at Cawnpur and elsewhere is chiefly used for the army and the police. In addition to these and the cotton and jute mills there are rice mills, timber mills, leather works, oil mills, iron and brass foundries, tile factories, printing presses, lac factories, silk mills, and paper mills. There is a large trade in wood-carving, the material being generally Indian ebony in northern India, sandal-wood in southern India, and teak in Burma and elsewhere.

The village brazier, like the village smith, manufactures the necessary vessels for domestic use. Chief among these vessels is the *lota*, or globular bowl, universally used in ceremonial ablutions. Benares enjoys the first reputation for work in brass and copper. In the south, Madura and Tanjore have a similar fame, and in the west, Ahmedabad, Poona and Nasik. Silver is sometimes mixed with the brass, and in rarer cases gold. The brass or rather bell-metal ware of Murshidabad, known as *khagrai*, has more than a local reputation, owing to the large admixture of silver in it.

Pottery.—Pottery is made in almost every village, from the small vessels required in cooking to the large jars used for storing grain and occasionally as floats to ferry persons across a swollen stream. Sind is the only province of India where the potter's craft is pursued with any regard to artistic considerations; its pottery is of two kinds, encaustic tiles and vessels for domestic use. In both cases, the colours are the same,—turquoise blue, copper green, dark purple or golden brown, under an exquisitely transparent glaze. The tiles, which are evidently of the same origin as those of Persia and Turkey, are chiefly to be found in the ruined mosques and tombs of the old Mussulman dynasties. Artistic pottery is made at Hyderabad, Karachi, Tatta and Hala, and also at Multan and Lahore in the Punjab. The Madura pottery deserves mention from the elegance of its form and the richness of its colour. The United Provinces have, among other specialties, an elegant black ware with designs in white metal worked into its surface.

Banking.—In another field an important step forward was taken in the amalgamation of the Presidency Banks of Bengal, Bombay and Madras into the Imperial Bank of India. This institution has taken over, at its London branch, the work which the Bank of England used to do for the government of India; it has also opened 100 new branches up-country to supplement the comparatively few branches of its constituents. Thus is established the coping-stone of the gravely inadequate banking system of the country. Next to the Imperial Bank come the exchange banks, whose main interests are in Europe or the Far East and who finance the Indian export trade as a supplement to their main operations. After them rank the Indian joint-stock banks, and lastly the scattered Indian bankers, brokers, marwaris, etc., whose operations are confined almost entirely to the interior of India. It is they who finance the movement of the crops to the ports, where the exchange banks take over the business. Despite

these ramifications, it is estimated that there are 500 towns in India with populations of 10,000 and upwards which have no modern banking facilities at all.

COMMUNICATIONS

Railways.—Indian railways serve at least three different purposes,—the ordinary business of carrying passengers and commerce; safeguarding the internal and external peace of the country; and protection against famine by facilitating the movement of grain. For this reason the interest on capital cannot, in the case of all the lines, be judged by a purely commercial standard: but for India as a whole the return on the capital expended is normally between $5\frac{1}{2}$ and 6 per cent. In the early days of railway enterprise the agency of private companies guaranteed by the state was exclusively employed, and nearly all the great trunk lines were built under this system. In 1870 a new policy of railway development by the direct agency of the state was inaugurated; and the government of India has often been criticized for lack of enterprise, undue complexity, and vacillation in its railway policy. But the tide is now running strongly in the direction of taking over under state control the main lines as the leases of their working companies fall in, or as the purchase powers under their original concessions mature. And, despite changes in policy, the broad fact remains that 39,000 m. of railroad have been constructed, for a capital outlay of £565 million, which convey passengers (nearly 600 millions in a year) at under one-third of a penny (3.47 pies) per mile as the average third-class fare, and goods at a little over a halfpenny (6.21 pies) per ton per mile.

There are roughly 19,000 m. of broad gauge ($5\frac{1}{2}$ feet) lines, 16,000 m. of metre-gauge, and 4,000 m. of narrow gauge. Of the total mileage 72 per cent are owned by the State and 40 per cent directly managed by it. The more extensive employment of Indians in the superior grades of the railway service is being rapidly pushed on, and a Railway Staff College is being established at Dehra Dun. The railway administration is under a Railway Board, with wide discretionary powers, and the finance of railways has now, to the marked advantage of the department, been separated from the general budget of the country.

Posts and Telegraphs.—In addition to its primary duties, this department has served miscellaneous functions. It acts as the people's savings-bank: and it allows the people to do their shopping at all distances through the system known as the V(alue) P(ayable) P(ost). It collects customs charges on dutiable articles coming to India by post. It has a life insurance department; it pays the pensions of retired officials of the Indian Army; and it sells quinine. In 1926 there were 20,000 post offices, and the number of postal-articles handled was 1,273 millions. There were 90,000 m. of telegraph line, and 16,000 state telephones were at work, besides 28,000 maintained by licensed companies in the larger cities. Telegraphic communication with Europe is maintained by the cable of the Eastern Telegraph Company *via* Aden, and by the Indo-European Department, working *via* Persia to Karachi. Wireless communication is being rapidly developed, and an extension of the Cairo-Basrah Air Mail service to Karachi will materially shorten intercourse between London and all parts of India.

HISTORY

For the early history of India the material is difficult but is steadily accumulating. Once we reach the Mohammedan period, information abounds; for Muslim literature is rich in annals and memoirs. But before A.D. 1000 the art of contemporary narrative hardly existed in India. The historical sense is not a feature of Hinduism; and while the orthodox Hindu takes no account of millennia, he accepts the *Mahabharata* as authentic history.

Sources of History.—The first exact date in the story is 326 B.C., the year when Alexander the Great invaded India; but even after that, there are long periods when the written record ceases and we have to revert to much the same sources as those on which we draw for the earlier eras. Those sources are fourfold. By far the most important hitherto has been the inscriptions on stone (caves, rocks and pillars) and on metal (mostly grants of

land), of which the volume is great, chiefly in southern India, though the dates are rarely more distant than Asoka. Coins form the next prolific source of information, though it is mostly dynastic in character and never of course of remote antiquity. Rapidly growing in importance is the study of buildings and monuments, more particularly on prehistoric sites which are now being explored. The excavations at Taxila, and those now being conducted at Mohenjo-Daro and Harappa, promise a flood of new light on the earlier Indian civilizations; and all over India there is an enormous mass of material waiting for the excavator of the future. The fourth source of history is the ancient literature and traditions of the country, if treated mainly as legends and wisely interpreted in the light of the surer facts deducible from the other sources. Besides these reservoirs of historical material, we get occasional help from the narratives of foreign travellers, such as the reports of Alexander's officers; the diaries of Megasthenes, of which long fragments have been preserved, when he resided at the Maurya court; the Greek pamphlet (c. A.D. 80) styled "Periplus of the Erythraean Sea"; and the writings of the Buddhist pilgrims from China who visited India in the Gupta period and again in Harsha's reign. But, at the best, much of the older history is based on skilled inference, and the margin for controversy among scholars remains considerable.

Earliest Civilizations.—Particularly is this true of estimates of the various layers of civilization which underlie the life of India today. There seems good reason to assume that, in the dim past, the country was widely occupied by an ancient pre-Dravidian race, of unknown origin but with Austric affinities; and that they were driven into the scattered hilly tracts where their purest survivals are still identifiable, and south of the Nerbudda, by another ancient race of a higher type which came in from outer Asia, probably through Baluchistan. The latter, popularly called the Dravidians, would seem to have developed a civilization of their own over a lengthened period, and in varying measure to have blended with, especially in south India, and to have absorbed or been absorbed by, the older inhabitants. Discoveries in the Indus valley indicate the existence of great cities, with traces of luxury and refinement which suggest affinities with the Sumerian, or even an earlier, culture, Sir John Marshall going so far as to put their standard of life higher than anything contemporary in Mesopotamia or Egypt. Some revision therefore is needed of the old conception of the Indo-Aryans finding themselves in a land of primitive savagery when they first descended through the passes of the north-west frontier, and started those long waves of immigration that flowed between 2400 and 1500 B.C. With the arrogance of a young and virile people, they may, as passages in the Vedas suggest, have scorned the older and complex civilization of a darker race; but that they were slowly drawn into it is clear, and the Dravidian reaction on the faith and life of the Indo-Aryans still awaits adequate judgment. It was apparently only in the Middle Land that they settled in force, roughly between the Indus and the Jumna; when they ventured further east, it was mainly in colonies surrounded by the older inhabitants, where, despite the inhibitions of earlier days, the purity of their blood slowly disappeared. That there was any penetration by the Indo-Aryans as such into peninsular India seems open to doubt. What did ultimately permeate into the south was the Hindu scheme of life which emerged from the racial blends that had matured in the north.

Vedic Times.—The *Rigveda* towers up as the great literary monument of the early Aryan settlements in the Punjab. Compiled possibly about A.D. 1200 or a little later from much older material, it is a collection of hymns, divided into ten books of unequal age, and approximating in length the *Iliad* and *Odyssey* combined. The more ancient hymns depict the invaders grouping on the Indus before they began to force their way into Hindustan. They were divided into various tribes, sometimes quarrelling among themselves, sometimes uniting against the "black-skinned" indigenes. Society with them still bears the imprint of the free life of their original homes. Caste, in its later sense, is unknown. Each father of a family is the priest of his own household. The chieftain acts as father and priest to the tribe;

but at the greater festivals he chooses some one specially learned in holy offerings to conduct the sacrifice in the name of the people. The chief himself seems to have been elected. Women enjoyed a high position, and some of the most beautiful hymns were composed by ladies and queens. Marriage was held sacred. Husband and wife were both "rulers of the house" (*dampati*), and drew near to the gods together in prayer. The burning of widows on their husbands' funeral-pile was unknown, and the verses in the *Veda* which the Brahmans afterwards distorted into a sanction for the practice have the very opposite meaning.

The Aryan tribes in the *Veda* are acquainted with most of the metals. They have blacksmiths, coppersmiths and goldsmiths among them, besides carpenters, barbers and other artisans. They fight from chariots, and freely use the horse, although not yet the elephant, in war. They have settled down as husbandmen, till their fields with the plough, and live in villages or towns. But others cling to their old wandering life, with their herds and "cattle-pens." Cattle, indeed, still form their chief wealth, the coin in which payments of fines are made; and one of their words for war literally means "a desire for cows." They have learned to build "ships," perhaps large river-boats, and seem to have heard something of the sea. Unlike the modern Hindus, the Aryans of the *Veda* ate beef, used a fermented liquor or beer made from the *soma* plant, and offered the same strong meat and drink to their gods. Thus the stout Aryans spread eastwards through northern India, pushed on from behind by later arrivals of their own stock, and driving before them, or reducing to bondage, or settling in amity beside, the earlier "black-skinned" races. They marched in whole communities from one river-valley to another, each house-father a warrior, husbandman and priest, with his wife and his little ones, and cattle.

Early States.—Of the political development of the country after the Indo-Aryans settled into their new homes, we know little: but before Buddhist times, the country between the Himalaya mountains and the Nerbudda river was divided into sixteen independent states, some monarchies and some tribal republics, the most important of which were the four monarchies of Kosala, Magadha, the Vamsas and Avanti. Kosala, the modern kingdom of Oudh, appears to have been the premier state of India in 600 B.C. Later the supremacy was reft from it by the kingdom of Magadha, the modern Behar (*q.v.*). South of Kosala lay the kingdom of the Vamsas, and south of that again the kingdom of Avanti. In the north-west was Gandhara, on the banks of the Indus, in the neighbourhood of Peshawar. The history of these early states is only a confused record of war and intermarriages, and is still semi-mythical. The list of the sixteen states ignores everything north of the Himalayas, south of the Vindhya, and east of the Ganges where it turns south.

Capital Cities.—The principal cities of India at this date were Ayōdhya, the capital of Kosala at the time of the Ramayana, though it afterwards gave place to Srāvastī, which was one of the six great cities of India in the time of Buddha. Baranasi, the modern Benares, had in the time of Megasthenes a circuit of 25 m. Kosambi, the capital of the Vamsas, lay on the Jumna, 230 m. up-stream from Benares. Rajagriha (Rajgir), the capital of Magadha, was built by Bimbisara, the contemporary of Buddha. Roruka, the capital of Sovira (? the Ophir of the Bible) was an important centre of the coasting trade. Saketa was sometime the capital of Kosala. Ujjayinī, the modern Ujjain, was the capital of Avanti.

The early Hindu writings classify mankind into four social grades on a basis of occupation: the Kshatriyas or nobles, who claimed descent from the early leaders; the Brahmans or learned and priestly order; the Vaisyas, the traders and peasantry; and last of all the Sudras, the hewers of wood and drawers of water, of non-Aryan descent. Below these there were low tribes and trades, aboriginal tribes and slaves. In later documents mention is made of eighteen gilds of work-people, whose names are nowhere given, but the complex institution of caste was of later date.

It is supposed that sea-going merchants, mostly Dravidians, and not Aryans, availing themselves of the monsoons, traded in the 7th century B.C. from the south-west ports of India to Baby-

lon, and that there they became acquainted with a Semitic alphabet, which they brought back with them, and from which all the alphabets now used in India, Burma, Siam and Ceylon have gradually evolved.

THE BUDDHIST PERIOD

The systems called Jainism and Buddhism had their roots in prehistoric philosophies, but were founded respectively by Vardhamana Mahavira and Gotama Buddha, both of whom were preaching in Magadha during the reign of Bimbisara (c. 520 B.C.).

The Emperor Asoka.—During the next two hundred years Buddhism spread over northern India, perhaps receiving a new impulse from the Greek kingdoms in the Punjab. About the middle of the 3rd century B.C. Asoka, the Maurya emperor who reigned from 264 B.C. to 227 B.C., became a zealous convert to Buddhism. He is said to have supported 64,000 Buddhist priests; he founded many religious houses, and his central kingdom is called the Land of the Monasteries (Vihara or Behar) to this day. He did for Buddhism what Constantine effected for Christianity; he organized it on the basis of a state religion. This he accomplished by five means—by a council to settle the faith, by edicts promulgating its principles, by a state department to watch over its purity, by missionaries to spread its doctrines, and by an authoritative collection of its sacred books. In 246 B.C. Asoka is said to have convened at Pataliputra (Patna) the third Buddhist council of one thousand elders (the tradition however rests on no actual evidence that we possess). In a number of edicts, both before and after the synod, he published throughout India the grand principles of the faith. Such edicts are still found graven deep upon pillars, in caves and on rocks, from the Yusafzai valley beyond Peshawar on the north-western frontier, through the heart of Hindustan, to Kathiawar and Mysore on the south and Orissa in the east. Tradition states that Asoka set up thousands of memorial columns; and the thirty-five inscriptions extant in our own day show how widely these royal sermons were spread over India. He created a special department to convert the aborigines, and he was equally vigilant of their material interests. Wells were to be dug and trees planted along the roads; a system of medical aid was established throughout his kingdom and the conquered provinces, as far as Ceylon, for both man and beast. Officers were appointed to watch over domestic life and public morality, and to promote instruction among the women as well as the youth.

Asoka recognized proselytism by peaceful means as a state duty. The rock inscriptions record how he sent forth missionaries "to the utmost limits of the barbarian countries," to "intermingle among all unbelievers" for the spread of religion. They shall mix equally with Brahmans and beggars, with the dreaded and the despised, both within the kingdom "and in foreign countries, teaching better things." Conversion is to be effected by persuasion, not by the sword. This character of a proselytizing faith which wins its victories by peaceful means has remained a prominent feature of Buddhism to the present day. Asoka, however, not only took measures to spread the religion; he also endeavoured to secure its orthodoxy. He collected the body of doctrine into an authoritative version, in the Magadhi language or dialect of his central kingdom in Behar—a version which for two thousand years has formed the canon (*pitakas*) of the southern Buddhists.

The fourth and last of the great councils was held in Kashmir under the Kushan king Kanishka (*see below*). This council, which consisted of five hundred members, compiled in the Sanskrit language three commentaries on the Buddhist faith. These commentaries supplied in part materials for the Tibetan or northern canon, drawn up at a subsequent period. The northern canon, or, as the Chinese proudly call it, the "greater vehicle of the law," includes many later corruptions or developments of the Indian faith as originally embodied by Asoka in the "lesser vehicle," or canon of the southern Buddhists.

Buddhism and Brahmanism.—Buddhism never ousted Brahmanism from any large part of India. The two systems co-existed as popular religions during more than a thousand years (250 B.C. to about A.D. 800). Certain kings and certain eras were intensely

Buddhistic; but the continuous existence of Brahmanism is abundantly proved from the time of Alexander (327 B.C.) downwards. The historians who chronicled his march, and the Greek ambassador Megasthenes, who succeeded them (300 B.C.) in their literary labours, bear witness to the predominance of the old faith in the period immediately preceding Asoka. Inscriptions, local legends, Sanskrit literature and the drama disclose the survival of Brahman influence during the next six centuries (250 B.C.—A.D. 400). From A.D. 400 we have the evidence of the Chinese pilgrims, who toiled through Central Asia into India as the birth-place of their faith. Fa-Hien entered India from Afghanistan, and journeyed down the whole Gangetic valley to the Bay of Bengal in A.D. 399–413. He found Brahman priests equally honoured with Buddhist monks, and temples to the Indian gods side by side with the religious houses of his own faith. Hsüan Tsang also travelled to India from China by the Central Asia route. His journey extended from A.D. 629 to 645, and everywhere throughout India he found the two faiths eagerly competing for the suffrages of the people. The monuments of the great Buddhist monarchs, Asoka and Kanishka, confronted him from the time he neared the Punjab frontier; but so also did the temples of Siva and his "dread" queen Bhima. Throughout north-western India he found Buddhist convents and monks surrounded by "swarms of heretics." The political power was also divided, although Buddhist sovereigns predominated. A Buddhist monarch ruled over ten kingdoms in Afghanistan. At Peshawar the great monastery built by Kanishka was deserted, but the populace remained faithful. In Kashmir king and people were devout Buddhists; in the country identified with Jaipur, on the other hand, the inhabitants were devoted to heresy and war.

Decline of Buddhism.—During the next few centuries Brahmanism gradually became the ruling religion. There are legends of persecutions instigated by Brahman reformers, such as Kumārila Bhatta and Sankara-Acharya. But the downfall of Buddhism seems to have resulted from natural decay, and from new movements of religious thought, rather than from any general suppression by the sword. Its extinction is contemporaneous with the rise of Hinduism, and belongs to a subsequent part of this sketch. In the 11th century, only outlying states, such as Kashmir and Orissa, remained faithful; and before the Mohammedans fairly came upon the scene Buddhism as a popular faith had disappeared from India. During the last ten centuries Buddhism has been a banished religion from its native home. But it has won greater triumphs in its exile than it could ever have achieved in the land of its birth. It has created a literature and a religion for more than a third of the human race, and has profoundly affected the beliefs of the rest. In India its influence has survived its separate existence: it supplied a basis upon which Brahmanism finally developed from the creed of a caste into the religion of the people.

HINDU PERIOD

The external history of India may be considered to begin with the Greek invasion in 327 B.C. Some indirect trade between India and the Levant existed from very ancient times. Homer was acquainted with tin and other articles of Indian merchandise by their Sanskrit names; and a long list has been made of Indian products mentioned in the Bible. In the time of Darius the valley of the Indus was a Persian satrapy. But the first Greek historian who speaks clearly of India was Hecataeus of Miletus (549–486 B.C.); the knowledge of Herodotus (450 B.C.) ended at the Indus; and Ctesias, the physician (401 B.C.), brought back from his residence in Persia only a few facts about the products of India, its dyes and fabrics, its monkeys and parrots. India to the east of the Indus was first made known in Europe by the historians and men of science who accompanied Alexander the Great in 327 B.C. Their narratives, although now lost, are condensed in Strabo, Pliny and Arrian.

Alexander's March.—Alexander the Great entered India early in 327 B.C. Crossing the lofty Khawak and Kaoshan passes of the Hindu Kush, he advanced by Alexandria, a city previously founded in the Koh-i-Daman, and Nicaea, another city to the west of Jalalabad, on the road from Kabul to India. Thence he turned

eastwards through the Kunar valley and Bajour, crossed the Gouraios (Panjkora) river, laid siege to Mount Aornos, and then moved over the Indus at Ohind, 16 m. above Attock, receiving there the submission of the great city of Taxila, represented by miles of ruins, which are now being systematically excavated, near the modern Rawalpindi. Crossing the Hydaspes (Jhelum) he defeated Porus in a great battle, and crossing the Acesines (Chenab) near the foot of the hills and the Hydraotes (Ravi), reached the Hypohasis (Beas). Here he was obliged by the temper of his army to retrace his steps, and retreat to the Jhelum, whence he sailed down the river to its confluence with the Indus, and thence to Patala, probably the modern Hyderabad. From Patala the admiral Nearchos was to sail round the coast to the Euphrates, while Alexander himself marched through the wilds of Gedrosia, or modern Makran. Ultimately, after suffering agonies of thirst in the desert, the army made its way back to the coast at the modern harbour of Pasni, whence the return to Susa in Persia was easy.

During his two years' campaign in the Punjab and Sind, Alexander captured no province, but he made alliances, founded cities and planted garrisons. He had transferred much territory to chiefs and confederacies devoted to his cause, and every petty court had its Greek faction. At Taxila (Dehri-Shahan) and Nicaea (Mong) in the northern Punjab, at Alexandria (Uchch) in the southern Punjab, at Patala (Hyderabad) in Sind, and at other points along his route, he established military settlements of Greeks or allies. A large body of his troops remained in Bactria; and, in the partition of the empire which followed Alexander's death in 323 B.C., Bactria and India eventually fell to Seleucus Nicator, the founder of the Syrian monarchy.

Chandragupta Maurya.—Meanwhile a new power had arisen in India. Among the Indian adventurers who thronged Alexander's camp in the Punjab, was Chandragupta Maurya, an exile from the Gangetic valley. In the confused years which followed Alexander's departure, he managed to form a kingdom on the ruins of the Nanda dynasty in Magadha or Behar (322 B.C.). He seized the capital, Pataliputra, the modern Patna, established himself firmly in the Gangetic valley, and compelled the north-western principalities, Greeks and natives alike, to acknowledge his suzerainty. While, therefore, Seleucus was winning his way to the Syrian monarchy, Chandragupta was building up an empire in northern India. Seleucus reigned in Syria from 312 to 280 B.C., Chandragupta in the Gangetic valley from 322 to 298 B.C. In 312 B.C. the power of both had been consolidated, and the two new sovereignties were brought face to face. Seleucus, having recovered Babylon, proceeded to re-establish his authority in Bactria and then moved on to India. There he met Chandragupta, now master of all Hindustan, with an immense army; and prudence decided him to ally himself with the new power in India rather than to oppose it. In return for five hundred elephants, he ceded the Greek settlements in the Punjab and the Kabul valley, gave his daughter to Chandragupta in marriage, and stationed an ambassador, Megasthenes, at the Gangetic court (302 B.C.). Chandragupta became familiar to the Greeks as Sandrocottus, king of the Prasii; his capital, Pataliputra, was called by them Palimbothra. On the other hand, the names of Greeks and kings of Grecian dynasties appear in the rock inscriptions, under Indian forms.

Previous to the time of Megasthenes the Greek idea of India was a very vague one; and it was he who first opened up the land to the western world. He describes the classification of the people, dividing them, however, into seven castes instead of four, namely, philosophers, husbandmen, shepherds, artisans, soldiers, inspectors and the counsellors of the king. The philosophers were the Brahmins, and the prescribed stages of their life are indicated. Megasthenes observes with admiration the absence of slavery in India, the chastity of the women, and the courage of the men. In valour they excelled all other Asiatics; they required no locks to their doors; above all, no Indian was ever known to tell a lie. Sober and industrious, good farmers and skilful artisans, they scarcely ever had recourse to a lawsuit, and lived peaceably under their native chiefs. The kingly government is portrayed almost as described in Manu, with its hereditary castes of councillors and soldiers. Megasthenes mentions that India was divided into one

hundred and eighteen kingdoms; some of which, such as that of the Prasii under Chandragupta, exercised suzerain powers.

The Brahmanism of northern India was destined to be profoundly influenced by the two powerful monarchies which sprung up toward the close of the fourth century B.C. On the east, in the Gangetic valley, Chandragupta firmly consolidated the dynasty which during the next century produced Asoka (264–228 or 227 B.C.), and established Buddhism throughout India. On the west, the Seleucids diffused Greek influences, and sent forth Graeco-Bactrian expeditions to the Punjab. Antiochus Theos (grandson of Seleucus Nicator) and Asoka (grandson of Chandragupta), who ruled these two monarchies in the 3rd century B.C., made a treaty with each other (256). In the next century Eucratides, king of Bactria, conquered as far as Alexander's royal city of Patala, and possibly sent expeditions into Cutch and Gujarat, 181–161 B.C. Of the Graeco-Indian monarchs, Menander advanced farthest into north-western India, and his coins are found from Kabul, near which he probably had his capital, as far as Muttra on the Jumna. The Buddhist dynasty of Chandragupta affected the religion of northern India from the east; the Seleucid empire, with its Bactrian and later offshoots, influenced the science and art of Hindustan from the west.

GREEK INFLUENCE

Astronomy and Art.—The Brahman astronomy owed much to the Greeks, and what the Buddhists were to the architecture of northern India, that the Greeks were to its sculpture. Greek faces and profiles constantly occur in ancient Buddhist statuary, and enrich almost all the larger museums in India. The purest specimens have been found in the North-West Frontier Province (the ancient Gandhara) and the Punjab, where the Greeks settled in greatest force. As we proceed eastward from the Punjab, the Greek type begins to fade. Purity of outline gives place to lusciousness of form. In the female figures, the artists trust more and more to swelling breasts and towering chignons, and load the neck with constantly accumulating jewels. Nevertheless, the Grecian type of countenance long survived in Indian art and it may even be traced in the delicate profiles on the so-called sun temple at Kanarak, built in the 12th century A.D. on the remote Orissa shore.

The Maurya Dynasty.—Chandragupta was one of the greatest of Indian kings. The dominions that he had won back from the Greeks he administered with equal power. He maintained an army of 600,000 infantry, 30,000 horsemen, 36,000 men with the elephants, and 24,000 men with the chariots, which was controlled by an elaborate war-office system. The account given of his reign by Megasthenes makes him better known to us than any other Indian monarch down to the time of Akbar. In 297 B.C. he was succeeded by his son, Bindusara, who is supposed to have extended his dominions down to Madras. In 272 B.C. he in turn was succeeded by Asoka, the Buddhist emperor, the religious side of whose reign has already been described. Asoka's empire included the greater part of Afghanistan, a large part of Baluchistan, Sind, Kashmir, Nepal, Bengal to the mouths of the Ganges, and peninsular India down to the Palar river. After Asoka the Mauryas dwindled away, and the last of them, Brihadratha, was treacherously assassinated in 184 B.C. by his commander-in-chief, Pushyamitra Sunga, who founded the Sunga dynasty.

BY COURTESY OF THE CANADIAN PACIFIC S.S. CO.

A DEVIL DANCER IN DARJEELING, IN THE EXTREME NORTH OF INDIA

Sunga, Kanva and Andhra Dynasties.—During the 2nd century B.C. north-western India was invaded and partially conquered by Antiochus III. the Great, Demetrius, Eucratides and Menander. With the last of these Pushyamitra Sunga waged successful war, driving him from the Gangetic valley and confining

him to his conquests in the west. Pushyamitra established his own paramountcy over northern India; but his reign is mainly memorable as marking the beginning of the Brahmanical reaction against Buddhism, and his savage persecution of the Buddhist monks. The Sunga dynasty, after lasting 112 years, was succeeded by the Kanva dynasty, which lasted 45 years, *i.e.*, until about 27 B.C., when it was overthrown by an unknown king of the Andhra dynasty of the Satavahanas, whose power, originating in the deltas of the Godavari and Kistna rivers, by A.D. 200 had spread across India to Nasik and gradually pushed its way northwards.

The Saka Satraps.—About A.D. 100 there appeared in the west three foreign tribes from the north, who established themselves in Malwa, Gujarat and Kathiawar. These tribes were the Sakas (Scythians), a horde of pastoral nomads from Central Asia, the Pahlavas, whose name is supposed to be a corruption of "Parthiva" (*i.e.*, Parthians of Persia), and the Yavanas (Ionians), *i.e.*, foreigners from the old Indo-Greek kingdoms of the north-west frontier, all of whom had been driven southwards by the advance of the Yueh-chi. Their rulers, of whom the first to be mentioned is Bhumaka, took the Persian title of satrap. They were hated by the Hindus as barbarians who disregarded the caste system and despised the holy law, and for centuries an intermittent struggle continued between the satraps and the Andhras, with varying fortune. Finally, however, about A.D. 236, the Andhra dynasty, after an existence of some 460 years, came to an end, and their place in western India was taken by the satraps, until the last of them was overthrown by Chandragupta Vikramaditya at the close of the 4th century.

The Kushan Dynasty.—Meanwhile, the Yueh-chi had themselves crossed the Hindu Kush to the invasion of north-western India. They were originally divided into five tribes, which were united under the rule of Kadphises I. (A.D. 40-78), the founder of the Kushan dynasty, who conquered the Kabul valley, annihilating what remained there of the Greek dominion, and swept away the petty Indo-Greek and Indo-Parthian principalities on the Indus. His successors completed the conquest of north-western India from the delta of the Indus eastwards probably as far as Benares. One effect of the Yueh-chi conquests was to open up a channel of commerce with the Roman empire by the northern trade routes; and the Indian embassy which, according to Dion Cassius (ix. 58), visited Trajan after his arrival at Rome in A.D. 99, was probably sent by Kadphises II. (Ooemokadphises) to announce his conquest of north-western India. The most celebrated of the Kushan kings, however, was Kanishka, whose date (c. A.D. 120) is still a matter of controversy. From his capital at Purushapura (Peshawar) he not only maintained his hold on north-western India, but conquered Kashmir, attacked Pataliputra, carried on a successful war with the Parthians, and led an army across the appalling passes of the Taghdumbash Pamir to the conquest of Kashgar, Yarkand and Khotan.

The dynasties of the Andhras in the centre and south and of the Kushans in the north came to an end almost at the same time (c. A.D. 236-225 respectively). The history of India during the remainder of the 3rd century is a confused record of meaningless names and disconnected events; and it is not until the opening of the 4th century that the veil is lifted, with the rise to supreme power in Magadha (A.D. 320) of Chandragupta I., the founder of the Gupta dynasty and empire.

The Gupta Age, 320 to 480 A.D.—Often described as the Golden Age of Hinduism, the Gupta period comprised the reigns of five great monarchs, who occupied an imperial throne, first at Pataliputra and afterwards at Ajodhya, for 160 years. The second of these, Samudragupta, a ruler of high personal accomplishments, brought under his sway the country from the Nerbudda on the south to the Himalayas on the north, from the Jumna on the west to the Brahmaputra on the east, and exercised considerable suzerainty even beyond those limits. Chandragupta II., the third of the line, was the Vikramajit of Indian legend. Under the last of the great five, Skandagupta, the pressure of the invading Huns began to break up the strongest power that gave India peace until the coming of Akbar. It was in peace and the arts of peace that the Gupta empire shone. The land was rich and prosperous; the

administration enlightened and tolerant; and Hindu art reached its zenith. Science was cultivated; music, sculpture and painting attained a high level of excellence. Literature flourished; it was under the Guptas that Kalidasa wrote his great play *Sakuntala*; and Sanskrit, as its vehicle, developed unequalled suppleness and grace. Trade extended in all directions, and diplomatic relations followed in its course; not less than three missions to imperial Rome figuring among the long tale of embassies sent by the Guptas to foreign courts. The Buddhist rule of life prevailed, Buddhism remaining in theory the State religion; but it was during this period that reviving Hinduism absorbed the best elements in Buddhism, and at the same time undermined its tenets by new orientations of Brahmanical philosophy.

The Hun Invasions.—The barbarian invasions of the fifth and sixth centuries, dismembering the Gupta empire and converting India into a Hun province, cut clean across the history and traditions of India. They began with the White Huns or Ephthalites, who after breaking (c. 470) the power of Persia and Kabul, swarmed across India in irresistible numbers. Their dominion was a mere organization for brigandage on an imperial scale and it did not long survive. It was shaken (c. 528) by the defeat, at the hands of tributary princes goaded to desperation, of Mihiragula, the most powerful and bloodthirsty of its rulers—the "Attila of India." It collapsed with the overthrow of the central power of the White Huns on the Oxus (c. 565) by the Turks. Though, however, this stopped the incursions of Asiatic hordes from the north-west, and India was to remain almost exempt from foreign invasion for some 500 years, the Ephthalite conquest added new and permanent elements to the Indian population. After the fall of the central power, the scattered Hunnish settlers, like so many before them, became rapidly Hinduized, and are probably the ancestors of some of the most famous Rajput clans.

Harsha.—The last Indian monarch, prior to the Mohammedan conquest, to establish and maintain paramount power in the north was Harsha, or Harshavardhana (also known as Siladitya), for whose reign (606-648) full and trustworthy materials exist in the book of travels written by the Chinese pilgrim Hsüan Tsang and the *Harsha-charita* (Deeds of Harsha) composed by Bana, a Brahman who lived at the royal court. Harsha was the younger son of the raja of Thanesar, and gained his first experience of campaigning while still a boy in the successful wars waged by his father and brother against the Huns on the north-western frontier. After the treacherous murder of his brother by Sasanka, king of Central Bengal, he spent five and a half years in continual warfare. By A.D. 612 he had actually conquered the north-western regions and also, probably, part of Bengal. After this he reigned for 34½ years, devoting most of his energy to perfecting the administration of his vast dominions. In his campaigns he was almost uniformly successful; but in his attempt to conquer the Deccan he was repulsed (620) by the Chalukya king, Pulikesin II., who successfully prevented him from forcing the passes of the Nerbudda. Towards the end of his reign Harsha's empire embraced the whole basin of the Ganges from the Himalayas to the Nerbudda, including Nepal, besides Malwa, Gujarat and Surashtra (Kathiawar); while even Assam (Kamarupa) was tributary to him. The empire, however, died with its founder. His benevolent despotism had healed the wounds inflicted by the barbarian invaders, and given to his subjects a false feeling of security. For he left no heir to carry on his work; his death was followed by centuries of disruptive internecine war.

The Deccan.—In the Deccan the middle of the 6th century saw the rise of the Chalukya dynasty, founded by Pulikesin I. about A.D. 550. The most famous monarch of this line was Pulikesin II., who repelled the inroads of Harsha (A.D. 620); but in A.D. 642 he was defeated by the Pallavas of Conjeeveram, and though his son Vikramaditya I. restored the fallen fortunes of his family, the Chalukyas were finally superseded by the Rashtrakutas about A.D. 750. The Kailas temple at Ellora was built in the reign of Krishna I. (c. A.D. 760). The last of the Rashtrakutas was overthrown in A.D. 973 by Taila II., a scion of the old Chalukya stock, who founded a second dynasty known as the Chalukyas of Kalyani, which lasted like its predecessor for about two centuries

and a quarter. About A.D. 1000 the Chalukya kingdom suffered severely from the invasion of the Chola king, Rajaraja the Great. Vikramanka, the hero of Bilhana's historical poem, came to the throne in A.D. 1076 and reigned for fifty years. After his death the Chalukya power declined. During the 12th and 13th centuries a family called Hoysala attained considerable prominence in the Mysore country, but they were overthrown by Malik Kafur in A.D. 1310. The Yadava kings of Deogiri were descendants of feudatory nobles of the Chalukya kingdom, but they, like the Hoysalas, were overthrown by Malik Kafur, and Ramachandra was the last independent Hindu sovereign of the Deccan.

The Kingdoms of the South.—According to ancient tradition the kingdoms of the south were three—Pandya, Chola and Chera. Pandya occupied the extremity of the peninsula, south of Pudukottai, Chola extended northwards to Nellore, and Chera lay to the west, including Malabar, and is identified with the Kerala of Asoka. All three kingdoms were occupied by races speaking Dravidian languages. The authentic history of the south does not begin until the 9th and 10th centuries A.D., though the kingdoms are known to have existed in Asoka's time.

The most ancient mention of the name Pandya occurs in the 4th century B.C., and in Asoka's time the kingdom was independent, but no early records survive, the inscriptions of the dynasty being of late date, while the long lists of kings in Tamil literature are untrustworthy. During the early centuries of the Christian era the Pandya and Chera kingdoms traded with Rome. The most ancient Pandya king to whom a definite date can be ascribed is Rajasimha (c. A.D. 920). Records begin towards the end of the 12th century, and the dynasty can be traced from then till the middle of the 16th century. The most conspicuous event in its history was the invasion by the Sinhalese armies of Parakramabahu, king of Ceylon (c. A.D. 1175). The early records of the Chera kingdom are still more meagre; and the authentic list of the rajas of Travancore does not begin till A.D. 1335.

The Chola kingdom, like the Pandya, is mentioned by the Sanskrit grammarian Katyayana in the 4th century B.C., and was recognized by Asoka as independent. The dynastic history of the Cholas begins about A.D. 860, and is known from then until its decline in the middle of the 13th century. During those four centuries their history is intertwined with that of the Pallavas, Chalukyas, Rashtrakutas and other minor dynasties. In A.D. 640 the Chola country was visited by Hsüan Tsang, but the country at that time was desolate, and the dynasty of small importance. In A.D. 985 Rajaraja the Great came to the throne, and after a reign of twenty-seven years died the paramount ruler of southern India. He conquered and annexed the island of Ceylon, and was succeeded by four equally vigorous members of the dynasty; but after the time of Vikrama (A.D. 1120) the Chola power gradually declined, and was practically extinguished by Malik Kafur.

The Pallava Confederacy.—Of the Pallavas, and the powerful part they played in the history of the peninsula, the records are scanty. The first Pallava king about whom anything substantial is known was Sivaskanda-Varman (c. A.D. 150), whose capital was Kanchi (Conjeeveram), his power extending into the Telugu country as far as the Kistna river. Two centuries later Samudragupta conquered eleven kings of the south, of whom three were Pallavas. It appears that in the 4th century three Pallava chiefs were established at Kanchi, Vengi and Palakkada, the latter two being subordinate to the first, and that Pallava rule extended from the Godavari on the north to the Southern Vellaru river on the south, and stretched across Mysore from sea to sea. About A.D. 609 Pulikesin II., the Chalukya king, defeated Mahendra-Varman, a Pallava chief, and drove him to take refuge behind the walls of Kanchi. About A.D. 620 a prince named Vishnuvardhana founded the Eastern Chalukya line in the province of Vengi, which was taken from the Pallavas. Hsüan Tsang visited Kanchi, the Pallava capital, in the year A.D. 640; the country was, according to his account, 1000 m. in circumference, and the capital was a large city 5 or 6 m. in circumference. In A.D. 642 the Pallavas defeated in turn Pulikesin II. The conflict became perennial, and when the Rashtrakutas supplanted the Chalukyas in the middle of the 8th century, they took up the old quarrel with the Pallavas.

Towards the end of the 10th century the Pallava power, which had lasted for ten centuries, was destroyed by the Chola monarch, Rajaraja the Great.

MOHAMMEDAN PERIOD

With northern India disrupted by the continual struggles of its warring Rajput chiefs, and southern India torn by its rival Dravidian principalities, all semblance of unity in the country had vanished before the sword of Islam was unsheathed. Warnings of the new danger came, and passed unheeded; for the Punjab was ravaged, and Sind was conquered by the Arabs, within a century of the death of the Prophet Mohammed. When at last India was seriously invaded by Subaktagin, Amir of Ghazni, a hurried effort was made to unite the Rajput powers, but it came too late, and Peshawar was thenceforth the advanced base for Muslim inroads. Subaktagin's son, Mahmud, extended the limits of his father's kingdom from Persia on the east to the Ganges on the west; and it is related that he led his armies into the plains of India no fewer than seventeen times. In 1001 he defeated Raja Jaipal a second time, and took him prisoner. But Anandpal, son of Jaipal, raised again the standard of national independence, and gathered an army of Rajput allies from the farthest corners of Hindustan. The decisive battle was fought in the valley of Peshawar. Mahmud won the day by the aid of his Turkish horsemen, and thenceforth the Punjab has been a Mohammedan province, except during the brief period of Sikh supremacy. The most famous of Mahmud's invasions of India was that undertaken in 1025–1026 against Gujarat. The goal of this expedition was the temple dedicated to Siva at Somnath. Tradition tells how Mahmud marched through Ajmere to avoid the desert of Sind; how he found the Hindus gathered on the neck of the peninsula of Somnath in defence of their holy city; how the battle lasted for two days; how in the end the Rajput warriors fled to their boats, while the Brahman priests retired into the inmost shrine; how Mahmud, introduced into this shrine, rejected all entreaties by the Brahmins to spare their idol, and all offers of ransom; how he smote the image with his club, and forthwith a fountain of precious stones gushed out. Until the British invasion of Afghanistan in 1839, the club of Mahmud and the wood gates of Somnath were preserved at the tomb of the great conqueror near Ghazni. The club has now disappeared, and the gates brought back to India by Lord Ellenborough are recognized to be a clumsy forgery. The Ghazni dynasty was a short one, and the Afghans of Ghor rose on its ruins. A cadet of this family, generally known in history as Mohammed Ghori, is the second of the great Mohammedan conquerors of India. In 1175 he took Multan and Uchch; in 1186 Lahore fell into his hands; in 1191 he was repulsed before Delhi, but soon afterwards he redeemed this disaster. By 1193 he had extended his conquests as far east as Benares, and the defeated Rajputs migrated in a body to the hills and deserts now known as Rajputana. In 1199 one of his lieutenants, named Bakhtiyar, advanced into Bengal, and expelled by an audacious stratagem the last Hindu raja of Nadia. The entire northern plain, from the Indus to the Brahmaputra, thus lay under the Mohammedan yoke. But Mohammed Ghori never settled permanently in India. His favourite residence is said to have been the old capital of Ghazni, while he governed his Indian conquests through the agency of a favourite slave, Kutb-ud-din.

The Slave Dynasty.—On the death of Mohammed Ghori (A.D. 1206), Kutb-ud-din at once laid aside the title of viceroy and proclaimed himself sultan of Delhi. He was founder of what is known as the slave dynasty, which lasted for nearly a century (1206–1288). From this period dates the *minar*, or pillar of victory, which still stands amid the ruins of ancient Delhi, towering high above all later structures. Kutb himself is said to have been successful as a general and an administrator, but none of his successors has left a mark in history.

In 1204 Ala-ud-din Khilji, the third of the great Mohammedan conquerors of India, raised himself to the throne of Delhi by the treacherous assassination of his uncle Feroz II. who had himself supplanted the last of the slave dynasty. Under the extensive schemes of conquest which he planned, one army was sent to

Gujarat, to conquer and expel the last Rajput king of Anhalwar or Patan. Another army, led by the sultan in person, marched into the heart of Rajputana, and stormed the rock-fortress of Chitor, where the Rajputs had taken refuge with their women and children. A third army, commanded by Malik Kafur, a Hindu renegade and favourite of Ala-ud-din, penetrated to the extreme south of the peninsula, scattering the unwarlike Dravidian races, and stripping every Hindu temple of its accumulations of gold and jewels.

Mohammed b. Tughlak.—Ala-ud-din died in 1316, having subjected to Islam the Deccan and Gujarat. Three successors followed him upon the throne, but their united reigns extended over only five years. In 1321 a successful revolt was headed by Ghiyas-ud-din Tughlak, governor of the Punjab, who is said to have been of Turkish origin. His son and successor, Mohammed b. Tughlak, reigned from 1325 to 1351. He conceived the project of transferring the seat of empire to the Deccan, and compelled the inhabitants of Delhi to remove a distance of 700 m. to Deogiri or Daulatabad. Mohammed was succeeded by his cousin Feroz, who likewise was not content without a new capital, which he placed a few miles north of Delhi, and called after his own name. Meanwhile the remote provinces of the empire began to throw off their allegiance to the sultans of Delhi. The independence of the Afghan kings of Bengal is generally dated from 1336, when Mohammed Tughlak was yet on the throne. The commencement of the reign of Ala-ud-din, the founder of the Bahmani dynasty in the Deccan, is assigned to 1347. Zafar Khan, the first of the Ahmedabad kings, acted as an independent ruler from his first appointment as governor of Gujarat in 1391.

Timur's Invasion.—Accordingly, when Timur (Tamerlane) invaded India in 1398, he encountered but little organized resistance. Delhi was sacked and the inhabitants massacred by the victorious Moghuls. The details of the fighting and of the atrocities may be found related in cold blood by Timur himself in the *Malfuzat-i-Timuri*, which has been translated in Elliot's *History of India as told by its own Historians*, vol. iii. Timur marched back to Samarkand as he had come, by way of Kabul, and Mahmud Tughlak ventured to return to his desolate capital. He was succeeded by what is known as the Sayyid dynasty, which held Delhi and a few miles of surrounding country for about forty years. The Sayyids were in their turn expelled by Bahlol, an Afghan of the Lodi tribe, whose successors removed the seat of government to Agra, which thus for the first time became the imperial city. In 1526 Babur, the fifth in descent from Timur, and also the fifth Mohammedan conqueror, invaded India at the instigation of the governor of the Punjab, won the victory of Panipat over Ibrahim, the last of the Lodi dynasty, and founded the Moghul empire, which lasted, at least in name, until 1857.

Vijayanagar.—In southern India at this time authentic history begins with the Hindu empire of Vijayanagar, which exercised an ill-defined sovereignty over the entire south from the 14th to the 16th century. The empire of Vijayanagar represents the last stand made by the national faith in India against conquering Islam. For at least two centuries its sway was undisputed.

The earliest of the Mohammedan dynasties in the Deccan was that founded by Ala-ud-din in 1347, which has received the name of the Bahmani dynasty. The capital was first at Gulbarga, and was afterwards removed to Bidar, both which places still possess magnificent palaces and mosques in ruins. Towards the close of the 14th century the Bahmani empire fell to pieces, and five independent kingdoms divided the Deccan among them. These were—(1) the Adil Shahi dynasty, with its capital at Bijapur, founded in 1490 by a Turk; (2) the Kutb Shahi dynasty, with its capital at Golconda, founded in 1512 by a Turkoman adventurer; (3) the Nizam Shahi dynasty, with its capital at Ahmednagar, founded in 1490 by a Brahman renegade; (4) the Imad Shahi dynasty of Berar, with its capital at Ellichpur, founded in 1484 also by a Hindu from Vijayanagar; (5) the Barid Shahi dynasty, with its capital at Bidar, founded about 1492 by one who is variously described as a Turk and a Georgian slave. In 1565 they combined against the Hindu raja of Vijayanagar, who was defeated and slain in the decisive battle of Talikota. But,

though the city was sacked and the supremacy of Vijayanagar for ever destroyed, the Mohammedan victors did not themselves advance far into the south. The Naiks or feudatories of Vijayanagar everywhere asserted their independence. One of the blood-royal of Vijayanagar fled to Chandragiri, and founded a line which exercised a prerogative of its former sovereignty by granting the site of Madras to the English in 1639. Another scion claiming the same high descent lingers to the present day near the ruins of Vijayanagar, and is known as the raja of Anagundi, a feudatory of the nizam of Hyderabad. Despite frequent internal strife, the sultans of the Deccan retained their independence until conquered by the Moghul emperor Aurangzeb in the latter half of the 17th century. To complete this sketch of India at the time of Baber's invasion it remains to say that an independent Mohammedan dynasty reigned at Ahmedabad in Gujarat for nearly two centuries (from 1391 to 1573), until conquered by Akbar; and that Bengal was similarly independent, under a line of Afghan kings, with Gaur for their capital, from 1336 to 1573.

The Moghul Dynasty.—In 1525 there descended upon India the most romantic figure in all her history, Babur, the young king of Kabul, who "laid the first stone of the splendid fabric" of the Moghul empire. On the famous field of Panipat he met the immense host of the Delhi Sultan; his own army was almost insignificant, but it was supported by artillery, seen for the first time in India, and it was brilliantly led. Prompt and complete was the triumph of the invader; Delhi and Agra were occupied; and Babur set himself to the task of subduing Hindu India, with the help of his Moghul comrades. A Rajput confederacy had been established, under the gallant Rana of Udaipur; and Babur met it in battle at Sikri near Agra. Before the attack, Babur solemnly abjured wine, his besetting sin, and then led his forces to victory. Thenceforward he never turned back; and by his death in 1530 his dominions extended from the Oxus to the frontier of Bengal and from the Himalayas to Gwalior. He was succeeded by his son Humayun, who is chiefly known as being the father of Akbar. In Humayun's reign the subject Afghans rose in revolt under Sher Shah, a native of Bengal, who for a short time established his authority over all Hindustan. Humayun was driven as an exile into Persia; and, while he was flying through the desert of Sind, his son Akbar was born to him in the petty fortress of Umarkot. But Sher Shah was killed at the storming of the rock-fortress of Kalinjar, and Humayun, after many vicissitudes, succeeded in re-establishing his authority at Lahore and Delhi.

Akbar.—Humayun died by an accident in 1556, leaving but a circumscribed kingdom, surrounded on every side by active foes, to his son Akbar, then a boy of only fourteen years. Akbar the Great, the real founder of the Moghul empire as it existed for two centuries, was the contemporary of Queen Elizabeth of England. He was born in 1542, and his reign lasted from 1556 to 1605. When his father died he was absent in the Punjab, fighting the revolted Afghans, under the guardianship of Bairam Khan, a native of Badakshan, whose military skill largely contributed to recover the throne for the Moghul line. For the first seven years of his reign Akbar was perpetually engaged in warfare. His first task was to establish his authority in the Punjab, and in the country around Delhi and Agra.

In 1567 he stormed the Rajput stronghold of Chitor, and conquered Ajmere. In 1570 he obtained possession of Oudh and Gwalior. In 1572 he marched in person into Gujarat, defeated the last of the independent sultans of Ahmedabad, and formed the province into a Moghul viceroyalty or subah. In the same year his generals drove out the Afghans from Bengal, and reunited the lower valley of the Ganges to Hindustan. Akbar was then the undisputed ruler of a larger portion of India than had ever before acknowledged the sway of one man. But he

BY COURTESY OF THE CANADIAN PACIFIC S.S. CO.

CONJURORS PLAYING FLUTES TO CHARM THE COBRAS

continued to extend his conquests throughout his lifetime. In 1578 Orissa was annexed to Bengal by his Hindu general Todar Mall, who forthwith organized a revenue survey of the whole province. Kabul submitted in 1581, Kashmir in 1587, Sind in 1592, and Kandahar in 1594. At last he turned his arms against the Mohammedan kings of the Deccan, and conquered Berar.

It is as a civil administrator that Akbar is remembered in India to the present day. With regard to the land revenue, the essence of his procedure was to fix the amount which the cultivators should pay at one-third of the gross produce, leaving it to their option to pay in money or in kind. As regards his military system, Akbar invented a sort of feudal organization, by which every tributary raja took his place by the side of his own Moghul nobles. In theory it was an aristocracy based only upon military command; but practically it accomplished the object at which it aimed by incorporating the hereditary chiefships of Rajputana among the mushroom creations of a Mohammedan despotism. The third and last of Akbar's characteristic measures were those connected with religious innovation, about which it is difficult to speak with precision. The necessity of conciliating the proud warriors of Rajputana had taught him toleration from his earliest days; and he was gradually led on by the stimulus of cosmopolitan discussion to question the truth of his inherited faith. The counsels of his friend Abul Fazl, coinciding with that sense of superhuman omnipotence which is bred of despotic power, led him at last to promulgate a new state religion, based upon natural theology, and comprising the best practices of all known creeds. In this strange faith Akbar himself was the prophet, or rather the head of the church. Every morning he worshipped the sun in public, as being the representative of the divine soul that animates the universe, while he was himself worshipped by the ignorant multitude.

Akbar died in 1605, in his sixty-third year. He was buried beneath a plain slab in the magnificent mausoleum which he had reared at Sikandra, near his capital of Agra.

Jahangir.—The reign of Jahangir, his son, extended from 1605 to 1627. It is chiefly remarkable for the influence exercised over the emperor by his favourite wife, surnamed Nur Jahan. The currency was struck in her name, and in her hands centred all the intrigues that made up the work of administration. She lies buried by the side of her husband at Lahore, whither the seat of government had been moved by Jahangir. It was in the reign of Jahangir that the English first established themselves at Surat, and also sent their first embassy to the Moghul court.

Shah Jahan.—Jahangir was succeeded by his son Shah Jahan, who had rebelled against his father, as Jahangir had rebelled against Akbar. Shah Jahan's reign is generally regarded as the period when the Moghul empire attained its greatest magnificence, though not its greatest extent of territory. He founded the existing city of Delhi, which is still known to its Mohammedan inhabitants as Shahjahanabad. At Delhi also he erected the celebrated peacock throne; but his favourite place of residence was Agra, where his name will ever be associated with the marvel of Indian architecture, the Taj Mahal. That jewel in marble was erected by Shah Jahan as the mausoleum of his favourite wife Mumtaz Mahal, and he himself lies by her side. Shah Jahan had four sons, of whom the third, Aurangzeb, by mingled treachery and violence, supplanted or overthrew his brothers and proclaimed himself emperor in 1658, while Shah Jahan was yet alive.

Aurangzeb.—Aurangzeb's long reign, from 1658 to 1707, may be regarded as representing both the culminating point of Moghul power and the beginning of its decay. Unattractive as his character was, it contained at least some elements of greatness. He was the first to conquer the independent sultans of the Deccan, and to extend his authority to the extreme south. But even during his lifetime two new Hindu nationalities were being formed in the Mahrattas and the Sikhs; while immediately after his death the nawabs of the Deccan, of Oudh and of Bengal raised themselves to practical independence. Aurangzeb had indeed enlarged the empire, but he had not strengthened its foundations. During the reign of his father Shah Jahan he had been viceroy of the Deccan or rather of the northern portion only, which had been annexed to the Moghul empire since the reign of Akbar. His early am-

bition was to conquer the Mohammedan kings of Bijapur and Golconda, who were practically supreme over the south.

This object was not accomplished without many hard-fought campaigns, in which Sivaji, the founder of the Mahratta confederacy, first comes upon the scene. In name Sivaji (whom Aurangzeb called the "mountain rat") was a feudatory of the house of Bijapur, on whose behalf he held the rock-forts of his native Ghats; but by sheer ability and courage he built up a great military power, based on masses of mobile horsemen, unequalled in guerilla warfare. A master of stratagem, he fought the Mohammedan generals with their own weapons, and carved out a kingdom which was to bulk largely in later history. As an enemy he was merciless and often treacherous: as ruler of his own people he was just and often generous. His memory is revered to this day as the acme of Hindu patriotism. In 1680 Sivaji died, and his son and successor, Sambhaji, was betrayed to Aurangzeb and put to death. The rising Mahratta power was thus for a time checked, and the Moghul armies were set free to operate in the eastern Deccan. In 1686 the city of Bijapur was taken by Aurangzeb in person, and in the following year Golconda also fell. No independent power then remained in the south. Early in his reign Aurangzeb had fixed his capital at Delhi, while he kept his de-throned father, Shah Jahan, in close confinement at Agra. In 1682 he set out with his army on his victorious march into the Deccan, and never again returned to Delhi. In this camp life Aurangzeb may be taken as representative of one aspect of the Moghul rule, which has been picturesquely described by European travellers of that day. They agree in depicting the emperor as a peripatetic sovereign, and the empire as held together by its military highways no less than by the strength of its armies. The Grand Trunk road running across the north of the peninsula, is generally attributed to the Afghan usurper, Sher Shah. The other roads branching out southward from Agra, to Surat and Burhanpur and Golconda, were undoubtedly the work of Moghul times. Each of these roads was laid out with avenues of trees, with wells of water, and with frequent *sardis* or rest-houses.

The Decline of the Moghul Empire.—On the death of Aurangzeb in 1707, the decline of the Moghul empire set in with extraordinary rapidity. Ten emperors after Aurangzeb are enumerated in the chronicles, but none of them has left any mark on history. In 1739 Nadir Shah of Persia, the sixth and last of the great Mohammedan conquerors of India, swept like a whirlwind over Hindustan, and sacked the imperial city of Delhi. Thenceforth the Great Moghul became a mere name, though the hereditary succession continued unbroken down to the time of the Mutiny. During the troubled period of intrigue and assassination that followed on the death of Aurangzeb, two Mohammedan foreigners rose to high position as courtiers and generals, and succeeded in transmitting their power to their sons. The one was Chin Kulich Khan, also called Asaf Jah, and still more commonly Nizam-ul-Mulk, who was of Turkoman origin, and belonged to the Sunni sect. His independence at Hyderabad in the Deccan dates from 1712. The other was Saadat Ali Khan, a Persian, and therefore a Shiah, who was appointed subahdar or nawab of Oudh about 1720. Thenceforth these two important provinces paid no more tribute to Delhi, though their hereditary rulers continued to seek formal recognition from the emperor on their succession. The Mahrattas were in possession of the entire west and great part of the centre of the peninsula; while the rich and unwarlike province of Bengal, though governed by an hereditary line of nawabs founded by Murshid Kuli Khan in 1704, still continued to pour its wealth into the imperial treasury. The central authority never recovered from the invasion of Nadir Shah in 1739, who carried off plunder variously estimated at from 8 to 30 millions sterling. The Mahrattas closed round Delhi from the south, and Ahmad Shah Durrani, a successor of Nadir Shah, came down from the west in quest of fresh plunder. After long skirmishing the two forces met at Panipat, and on January 7, 1761, they fought for the empire. The Mahrattas were disastrously routed: but the Durrani could not keep his troops from turning homewards to Kabul, and puppets continued on the Moghul throne until the last of them, Bahadur Shah, was banished to Burma in 1857.

EARLY EUROPEAN SETTLEMENTS

A Portuguese expedition under Vasco da Gama started from Lisbon in the year 1497, and, doubling the Cape of Good Hope, cast anchor off the city of Calicut on the 20th of May 1498, after a prolonged voyage of nearly eleven months.

Portuguese Expeditions.—After staying nearly six months on the Malabar coast, da Gama returned to Europe by the same route as he had come, bearing with him the following letter from the zamorin, or Hindu raja of Malabar, to the king of Portugal: "Vasco da Gama, a nobleman of your household, has visited my kingdom and has given me great pleasure. In my kingdom there is abundance of cinnamon, cloves, ginger, pepper, and precious stones. What I seek from thy country is gold, silver, coral and scarlet." The arrival of da Gama at Lisbon was celebrated with great rejoicings. A second expedition, consisting of thirteen ships and twelve hundred soldiers, under the command of Cabral, was despatched in 1500. Ultimately he reached Calicut, and established factories both there and at Cochin, in the face of active hostility from the Indians. In 1502 the king of Portugal obtained from Pope Alexander VI. a bull constituting him "lord of the navigation, conquest, and trade of Ethiopia, Arabia, Persia, and India." In that year Vasco da Gama sailed again to the East, with a fleet numbering twenty vessels. He formed an alliance with the rajas of Cochin and Cannamore against the zamorin of Calicut, and bombarded the latter in his palace. In 1503 the great Alfonso d'Albuquerque is first heard of, as in command of one of three expeditions from Portugal. In 1505 a large fleet of twenty sail and fifteen hundred men was sent under Francisco de Almeida, the first Portuguese viceroy of India. In 1509 Albuquerque succeeded as governor, and widely extended the area of Portuguese influence. Having failed in an attack upon Calicut, he seized Goa, which from 1530 became the capital of Portuguese India. Then, sailing round Ceylon, he captured Malacca, the key of the navigation of the Indian archipelago, and opened a trade with Siam and the Spice Islands (Moluccas). Lastly, he sailed back westwards, and, after penetrating into the Red Sea, and building a fortress at Ormuz in the Persian Gulf, returned to Goa only to die in 1515. In 1524 Vasco da Gama came out to the East for the third time, and he too died at Cochin.

Decline of the Portuguese.—For exactly a century, from 1500 to 1600, the Portuguese enjoyed a monopoly of Oriental trade. Their three objects were conquest, commerce and conversion, and for all three their position on the Malabar coast strip was remarkably well adapted. Their trade relations with Vijayanagar were very close, when that great empire was at the height of its power; but with its fall began the decline of Portugal. During the whole of the 16th century the Portuguese disputed with the Mohammedans the supremacy of the Indian seas. After the middle of the 17th century the Asiatic trade of Portugal practically disappeared, and now only Goa, Daman and Diu are left to her as relics of her former greatness.

Dutch Settlements.—The Dutch were the first European nation to break through the Portuguese monopoly. During the 16th century Bruges, Antwerp and Amsterdam became the great emporia whence Indian produce, imported by the Portuguese, was distributed to Germany and even to England. Private companies for trade with the East were formed in many parts of the United Provinces, but in 1602 they were all amalgamated by the states-general into "The United East India Company of the Netherlands." Within a few years the Dutch had established factories on the continent of India, in Ceylon, in Sumatra, on the Persian Gulf and on the Red Sea, besides having obtained exclusive possession of the Moluccas. In 1618 they laid the foundation of the city of Batavia in Java. In the far East the Dutch ruled without a rival, and gradually expelled the Portuguese from almost all their territorial possessions.

Decline of the Dutch.—The knell of Dutch supremacy was sounded by Clive, when in 1758 he attacked the Dutch at Chinsura by land and water, and forced them to an ignominious capitulation. In the great French war from 1781 to 1811 England wrested from Holland every one of her colonies, though Java was restored in 1816 and Sumatra in exchange for Malacca in 1824. At the

present time the Dutch flag flies nowhere on the mainland of India.

British Expeditions.—The earliest English attempts to reach the East were the expeditions under John Cabot in 1497 and 1498. Their objective was not so much India as Japan (Cipangu), of which they only knew vaguely as a land of spices and silks, and which they hoped to reach by sailing westward. They failed, but discovered Newfoundland, and sailed along the coast of America from Labrador to Virginia. In 1553 the ill-fated Sir Hugh Willoughby attempted to force a passage along the north of Europe and Asia; and many subsequent attempts were made at the North-West Passage from 1576 to 1616.

East India Company.—The "Governor and Company of Merchants of London trading into the East Indies" was founded by Queen Elizabeth on the last day of 1600, and the first expedition of four ships under James Lancaster left Torbay towards the end of April 1601, and reached Achin in Sumatra on the 5th of June 1602, returning with a cargo of spices. Soon the English began to feel their way towards the mainland of India itself. In 1608 Captain Hawkins visited Jahangir at Agra, and obtained permission to build a factory at Surat. Wherever the English went they were met by the hostility of the Portuguese; and on the 29th of November 1612 the Portuguese admiral with four ships attempted to capture the English vessels under Captain Best at Swally, off the mouth of the Tapti river; but the Portuguese were severely defeated, and the action formed the beginning of British maritime supremacy in Indian seas. The first fruits of the victory were the foundation of a factory at Surat and at other places round the Gulf of Cambay and in the interior. From the imperial firman of December 1612 dates the British settlement on the mainland of India.

Rivalry with Portugal.—The ten years that elapsed between the battle of Swally and the British capture of Ormuz in 1622 sufficed to decide the issue in the struggle for supremacy between the British and the Portuguese. The latter, unwillingly linked to the dying power of Spain, were already decadent, and on the 20th of January 1615 a great Portuguese armada, consisting of six great galleons, three smaller ships, two galleys and sixty rowed barges, was defeated in another action in Swally roads by Captain Nicholas Downton, in command of four British vessels. In 1618 the English opened trade between Surat and Jask in the Persian Gulf, and in 1620 gained a victory over the Portuguese fleet there. Early in 1622 the English fleet gained a second decisive victory, and captured Ormuz, the pearl of the Portuguese possessions in Asia.

Rivalry with the Dutch.—The struggle with the young and growing power of Holland was destined to be a much more serious affair than that with the exhausted power of Portugal. They were already too strongly entrenched in the Indian archipelago for English competition to avail there, and the intense rivalry between the two nations led to the tragedy of Amboyna in 1623, when Governor Van Speult put to torture and death nine Englishmen on a charge of conspiring to take the Dutch forts. This outrage was not avenged until the time of Cromwell (1654), and in the meantime the English abandoned the struggle for the Spice Islands, and turned their attention entirely to the mainland of India. In 1616 the Dutch began to compete with the English at Surat, and their piracies against native vessels led to the Moghul governor seizing English warehouses; but soon the Indian authorities learnt to discriminate between the different European nations, and the methods of the Dutch brought them into disfavour.

Madras Settlements.—In 1611 Captain Hippon founded the first English settlement (Pettapoli) in the Bay of Bengal, which finally perished through pestilence in 1687. In 1639 Francis Day founded Madras, building Fort St. George (1640), and transferring thither the chief factory from Masulipatam. Here the English obtained their first grant of Indian soil, apart from the plots on which their factories were built. In 1653 Madras was raised to an independent presidency, and in 1658 all the settlements in Bengal and on the Coromandel coast were made subordinate to Fort St. George.

Bengal Settlements.—In 1633 eight Englishmen from Masul-

ipatam, under Ralph Cartwright, sailed northward to Harishpur near Cuttack on the mouth of the Mahanadi, and entered into negotiations to trade with the governor of Orissa; and in June 1633 Cartwright founded a factory at Balasore, which proved very unhealthy. In 1651 the English reached Hugli, which was at that time the chief port of Bengal; about that year Gabriel Boughton, a surgeon, obtained from the Moghul viceroy permission for the English to trade in Bengal. In 1657 Hugli became the head agency in Bengal, with Balasore and Cossimbazar in the Gangetic delta and Patna in Behar under its control. In that year the name of Job Charnock, the future founder of Calcutta, appeared in the lowest grade of the staff.

Acquisition of Bombay.—The company had long fixed an eye on Bombay. Its position half way down the Indian seaboard gave it both strategic and commercial importance, while it lay beyond the authority of the Moghuls, and so could be fortified without offending them. In 1661 Charles II. received Bombay from Portugal as part of the Infanta Catherine's dowry, but effective possession was not taken until 1665, and in 1668 Charles handed the island over to the company. In the year 1670 Gerald Aungier fortified the island, and so became the true founder of its prosperity. In 1674 a treaty was entered into with Sivaji. In 1682 Sir Josiah Child at home and Sir John Child in India formed a combination, which recognized that in the struggle between the Moghul and the Mahrattas the English must meet force with force; and in 1687 Bombay supplanted Surat as the chief seat of the English in India.

The Founding of Calcutta.—In 1679 the English obtained from the Moghul emperor a firman exempting them from dues everywhere except at Surat; but Shaista Khan, the viceroy of Bengal, refused to recognize the document, and on the 14th of January 1686 the court of directors resolved to have recourse to arms to effect what they could not obtain by treaty. An expedition was despatched to India consisting of six companies of infantry and ten ships under Captain Nicholson. Two of the ships with 308 soldiers arrived at the Hugli river in the autumn of 1686. At this time Job Charnock was the chief of the Bengal council, and, owing to an affray with the Moghul troops at Hugli on the 28th of October 1686, he embarked the company's goods and servants on board light vessels and dropped down the river to Sutanati, the site of the modern Calcutta. At this place, about 70 m. from the sea and accessible at high tide to heavily armed ships, the stream had scooped for itself a long deep pool, now Calcutta harbour, while the position was well chosen to make a stand against the Bengal viceroy. On the 20th of December 1686 Charnock first settled at Calcutta, but in the following February Shaista Khan despatched an army against him, and he was forced to drop farther down the river to Hijili. In June Charnock capitulated and returned to Ulubaria, 16 m. below Calcutta, thence moving in September to Calcutta for the second time. On the 8th of November 1688 Captain Heath arrived with orders from England, and took away Charnock against his will; but after peace was restored between the Moghul emperor and the company in February 1690, Charnock returned to Calcutta for the third and last time on the 24th of August of that year. It was thus that the modern capital of India was eventually founded.

INDIA UNDER THE COMPANY

The political history of the British in India begins in the 18th century and in the struggle for dominion with the French. On the death of Aurangzeb in 1707, the whole of southern India had become practically independent of Delhi. In the Deccan proper, the Nizam-ul-Mulk founded an independent dynasty, with Hyderabad for its capital, which exercised a nominal sovereignty over the entire south. The Carnatic was ruled by a deputy of the nizam, known as the nawab of Arcot. Farther south, Trichinopoly

was the capital of a Hindu raja, and Tanjore formed another Hindu kingdom under a degenerate descendant of the line of Sivaji. Inland, Mysore was gradually growing into a third Hindu state.

French and British Wars.—Such was the condition of affairs when the French carried the War of the Austrian Succession into India. Dupleix was at that time governor of Pondicherry and Clive was a young writer at Madras. In 1746 a French squadron arrived, under the command of La Bourdonnais. Madras surrendered almost without a blow, and the only settlement left to the British was Fort St. David, a few miles south of Pondicherry, where Clive and a few other fugitives sought shelter. In 1748 a British fleet arrived under Admiral Boscawen and attempted the siege of Pondicherry, while a land force co-operated under Major Stringer Lawrence. The French successfully repulsed all attacks, and at last peace was restored by the treaty of Aix-la-Chapelle, which gave back Madras to the British (1748).

Clive.—The first war with the French was merely an incident in the greater contest in Europe. The second war had its origin in Indian politics, while England and France were at peace. The easy success of the French arms had inspired Dupleix with the ambition of founding a French empire in India, under the shadow of the existing Mohammedan powers. Disputed successions at Hyderabad and at Arcot supplied his opportunity. In the latter case the French and English espoused rival candidates. In the war that ensued the one incident that stands out conspicuously is the capture and subsequent defence of Arcot by Clive in 1751. This heroic feat, even more than the battle of Plassey, established the reputation of British valour throughout India. British influence predominated in the Carnatic, but the French were no less supreme in the Deccan, whence they were able to take possession of the coast tract called "the Northern Circars." The final struggle was postponed until 1760, when Colonel (afterwards Sir Eyre) Coote won the decisive victory of Wandiwash over the French general Lally, and proceeded to invest Pondicherry, which was starved into capitulation in January 1761.

Meanwhile the interest of history shifts with Clive to Bengal, where British, French and Dutch were established, with their headquarters respectively at Calcutta, Chandernagore and Chinsura, all three towns being situated close to each other in the lower reaches of the Hugli, where the river is navigable for large ships. The last great nawab or governor of Bengal was Ali Vardi Khan, in whose days the Mahratta horsemen began to ravage the country, and the British at Calcutta obtained permission to erect an earth-work, which is known to the present day as the Mahratta ditch. Ali Vardi Khan died in 1756, and was succeeded by his grandson, Suraj-ud-Dowla, a youth of only nineteen years, whose ungovernable temper led to a rupture with the British within two months after his accession. In pursuit of one of his own family who had escaped from his vengeance, he marched upon Calcutta with a large army. Many of the British fled down the river in their ships. The remainder surrendered after a feeble resistance, and were thrown as prisoners into the "black hole" or military jail of Fort William, a room 18 ft. by 14 ft. 10 in. in size, with only two small windows barred with iron. It was the month of June, in which the tropical heat of Calcutta is most oppressive. When the door of the prison was opened in the morning, only twenty-three persons out of one hundred and forty-six were found alive.

Battle of Plassey.—The news of this disaster fortunately found Clive returned to Madras, where also was a squadron of king's ships under Admiral Watson. Clive and Watson promptly sailed to the mouth of the Ganges with all the troops that could be got together. Calcutta was recovered with little fighting, and Clive then moved up the river and captured Chandernagore. Finally he marched out to give battle to Suraj-ud-Dowla on the field of Plassey (Palasi), at the head of about 900 Europeans and 2,000 sepoys, with 8 pieces of artillery. The Mohammedan army is said to have consisted of 35,000 foot, 15,000 horse and 50 pieces of cannon. But there was a traitor in the Mohammedan camp in the person of Mir Jafar, who had married a sister of the late nawab, Ali Vardi Khan. The battle was short but decisive. After

BY COURTESY OF N. BAPTIST CONV.

brief artillery fire, Suraj-ud-Dowla fled, and the foundations of the British Empire in India were laid (23rd June, 1757).

In place of Suraj-ud-Dowla Clive obtained a patent of investiture from the Moghul court in favour of his nominee Mir Jafar as governor of Bengal. Enormous sums were exacted from Mir Jafar as the price of his elevation; and the nawab made a grant to the company of the *zamindari* rights over an extensive tract of country (about 882 sq.m.) round Calcutta, now known as the district of the Twenty-four Parganas. The superior lordship, or right to receive the quit rent, remained with the nawab; but in 1759 this also was parted with by the nawab in favour of Clive, who thus became the landlord of his own masters, the company. On Clive's death his land passed to the company, thus merging the *zamindari* in the proprietary rights.

Massacre of Patna.—In 1758 Clive was appointed by the court of directors to be governor of all the company's settlements in Bengal; and in 1760 he left India. For the next five years the history of the British in Bengal contains little that is creditable. In 1761 it was found expedient and profitable to dethrone Mir Jafar, the nawab of Murshidabad, and substitute his son-in-law, Mir Kasim, in his place. On that occasion, besides private donations, the British received a grant of the three districts of Burdwan, Midnapur and Chittagong, estimated to yield a net revenue of half a million sterling. But Mir Kasim proved to possess a will of his own, and to cherish dreams of independence. He retired from Murshidabad to Monghyr, a strong position on the Ganges, which commanded the only means of communication with Upper India. There he proceeded to organize an army, drilled and equipped after European models, to carry on intrigues with the nawab wazir of Oudh, and finally to attack the company's settlements. When regular warfare began Mir Kasim met with no more successes. His trained regiments were defeated in two pitched battles by Major Adams, at Gheria and at Udhana, and he himself took refuge with the nawab wazir of Oudh, who refused to deliver him up. This led to a prolongation of the war. Shah Alam, who had now succeeded his father as emperor, and Shuja-ud-Daula, the nawab wazir of Oudh, united their forces, and threatened Patna, which the British had recovered. In 1764 Major (afterwards Sir Hector) Munro won the decisive battle of Buxar, which laid Oudh at the feet of the conquerors, and brought the Moghul emperor as a suppliant to the British camp.

Clive's Reforms.—Meanwhile the council at Calcutta had twice found the opportunity they desired of selling the government of Bengal to a new nawab. But in 1765 Clive (now Baron Clive of Plassey, in the peerage of Ireland) arrived at Calcutta, as governor of Bengal for the second time. Two objects stand out conspicuously in his policy. First, he sought to acquire the substance, though not the name, of territorial power, by using the authority of the Moghul emperor for so much as he wished, and for no more; and, secondly, he desired to purify the company's service by prohibiting illicit gains, and at the same time guaranteeing a reasonable remuneration from honest sources. Clive's first step was to hurry up from Calcutta to Allahabad, and there settle in person the fate of half northern India. Oudh was given back to the nawab wazir, on condition of his paying half a million sterling towards the expenses of the war. The provinces of Allahabad and Kora, forming the lower part of the Doab, were handed over to Shah Alam himself, who in his turn granted to the company the *diwani* or financial administration of Bengal, Behar and Orissa, together with the Northern Circars. In attempting to reorganize and purify the company's service, Clive undertook a task yet more difficult. Despite the resistance of the civil servants, and an actual mutiny of two hundred military officers, Clive carried through his reforms. Private trade and the receipt of presents were prohibited, while a substantial increase of pay was provided out of the monopoly of salt.

Warren Hastings.—Lord Clive quitted India for the third and last time in 1767. Five years later Warren Hastings was nominated governor by the court of directors, with instructions to carry out a predetermined series of reforms. He removed the exchequer from Murshidabad to Calcutta, and for the first time appointed European officers, under the now familiar title of col-

lectors, to superintend the revenue collections and preside in the civil courts. The reform of civil administration was finally accomplished by Lord Cornwallis.

From 1772 to 1774 Hastings was governor of Bengal; from 1774 to 1785 he was the first titular governor-general of India. In his domestic policy he was greatly hampered by the opposition of Sir Philip Francis; but, so far as regards external relations with Oudh, with the Mahrattas, and with Hyder Ali, he was generally able to compel assent to his own measures.

Rise of the Mahrattas.—Sivaji the Great, as already mentioned, died in 1680, while Aurangzeb was still on the throne. All real power passed into the hands of the peshwa, or Brahman minister, who founded in his turn an hereditary dynasty at Poona, dating from the beginning of the 18th century. Next rose several Mahratta generals, who, though recognizing the suzerainty of the peshwa, carved out for themselves independent kingdoms in different parts of India, sometimes far from the original home of the Mahratta race. Chief among these generals were the Gaikwar in Gujarat, Sindhia and Holkar in Malwa, and the Bhonsla raja of Berar and Nagpur. The Mahrattas were the most formidable military power in India.

First Mahratta War.—The Bombay government was naturally emulous to follow the example of Madras and Bengal, and to establish its influence at the court of Poona by placing its own nominee upon the throne. The attempt took form in 1775 in the treaty of Surat, by which Raghunath Rao, one of the claimants to the throne of the peshwa, agreed to cede Salsette and Bassein to the British, in consideration of being himself restored to Poona. The military operations that followed are known as the first Mahratta War. Warren Hastings threw the whole force of the Bengal army into the scale. One of his favourite officers, General Goddard, marched across the peninsula, and conquered the rich province of Gujarat almost without a blow. Another, Captain Popham, stormed the rock-fortress of Gwalior, which was regarded as the key of Hindustan. These brilliant successes atoned for the disgrace of the convention of Wargaoon in 1779, when the Mahrattas dictated terms to a Bombay force, but the war was protracted until 1782. It was then closed by the treaty of Salbai. Raghunath Rao was set aside; Gujarat was restored, and only Salsette and some other small islands were retained by the English.

First Mysore War.—Meanwhile Warren Hastings had to deal with a more formidable enemy than the Mahratta confederacy. The reckless conduct of the Madras government had roused the hostility both of Hyder Ali of Mysore and of the nizam of the Deccan, the two strongest Mussulman powers in India, who attempted to draw the Mahrattas into an alliance against the British. The diplomacy of Hastings won over the nizam and the Mahratta raja of Nagpur, but the army of Hyder Ali fell like a thunderbolt upon the British possessions in the Carnatic. A strong detachment under Colonel Baillie was cut to pieces at Perambakam, and the Mysore cavalry ravaged the country unchecked up to the walls of Madras. For the second time the Bengal army, stimulated by the energy of Hastings, saved the honour of the British name. Sir Eyre Coote, the victor of Wandiwash, was sent by sea to relieve Madras. The war was hotly contested. Hyder died in 1782, and peace was concluded with Tippoo in 1784, on the basis of a mutual restitution of all conquests.

Permanent Settlement of Bengal.—Warren Hastings was governor or governor-general for thirteen years. He was succeeded by Lord Cornwallis, the first English nobleman of rank to become governor-general. His rule lasted from 1786 to 1793, and is celebrated for two events—the introduction of the permanent settlement into Bengal and the second Mysore war. It was he who first entrusted criminal jurisdiction to Europeans, and established the appellate court of criminal judicature at Calcutta. But the achievement most familiarly associated with the name of Cornwallis is the permanent settlement of the land revenue of Bengal. Up to this time the revenue had been collected pretty much according to the old Moghul system. *Zamindars*, or government tax farmers, whose office always tended to become

hereditary, were recognized as having a right of some sort to collect the revenue from the actual cultivators. But no principle of assessment existed, and the amount actually realized varied greatly from year to year. Cornwallis took out with him in 1787 instructions to introduce a permanent settlement. The assessment began in 1789 and terminated in 1791. At first the settlement was called decennial, but in 1793 it was declared permanent for ever. The total assessment amounted to about 2½ millions sterling.

Second Mysore War.—The second Mysore War of 1790–92 is noteworthy on two accounts: Lord Cornwallis, the governor-general, led the British army. The nizam of the Deccan and the Mahratta confederacy, co-operated as allies of the British. In the result, Tippoo Sultan submitted, and agreed to yield one-half of his dominions to be divided among the allies, and to pay three millions sterling towards the cost of the war.

The period of Sir John Shore's rule as governor-general, from 1793 to 1798, was uneventful. In 1798 Lord Mornington, better known as the marquis Wellesley, arrived in India, already inspired with imperial projects that were destined to change the map of the country. From the first he laid down as his guiding principle that the British must be the one paramount power in the peninsula, and that the Indian princes could only retain the insignia of sovereignty by surrendering the substance of independence. This policy received its finishing touch when Queen Victoria was proclaimed empress of India in 1877.

The French Menace.—To frustrate the possibility of a French invasion of India, led by Napoleon in person, was the governing idea of Wellesley's foreign policy. Napoleon was in Egypt, dreaming of the conquests of Alexander; and no man knew in what direction he might turn his hitherto unconquered legions. Wellesley first addressed himself to the nizam, where his policy prevailed without serious opposition. He then turned against Tippoo, whom Cornwallis had defeated but not subdued. His intrigues with the French were laid bare, and he was given an opportunity of adhering to the new subsidiary system. On his refusal war was declared. Tippoo, after offering but a feeble resistance in the field, retired into Seringapatam, and, when his capital was stormed, died fighting bravely in the breach (1799). Since the battle of Plassey no event so greatly impressed the native imagination as the capture of Seringapatam, which won for General Harris a peerage and for Wellesley an Irish marquissate. In dealing with the territories of Tippoo, Wellesley acted with moderation. The central portion, forming the old state of Mysore, was restored to an infant representative of the Hindu rajas, whom Hyder Ali had dethroned, while the rest was partitioned between the nizam and the British. At about the same time the province of the Carnatic, or all that large portion of southern India ruled by the nawab of Arcot, and also the principality of Tanjore, were placed under direct British administration, making the Madras presidency almost what it is to-day.

Wars with Sindhia and Holkar.—The Mahrattas had now formed a confederacy of five powers. The recognized head of the confederacy was the peshwa of Poona, who ruled the hill country of the Western Ghats, the cradle of the Mahratta race. The fertile province of Gujarat was annually harried by the horsemen of the Gaekwar of Baroda. In central India two military leaders, Sindhia of Gwalior and Holkar of Indore, alternately held the pre-eminence. Towards the east the Bhonsla raja of Nagpur reigned from Berar to the coast of Orissa. Wellesley tried assiduously to bring these several Mahratta powers within the net of his subsidiary system. The plan and provision of resources were due to the marquis Wellesley. The armies were led by General Arthur Wellesley (afterwards duke of Wellington) and General (afterwards Lord) Lake. Wellesley operated in the Deccan, where, in a few short months, he won the decisive victories of Assaye and Argaum. Lake's campaign in Hindustan was as brilliant. He won pitched battles at Aligarh and Laswari, and captured the cities of Delhi and Agra. Before the year 1803 was out, both Sindhia and the Bhonsla raja were glad to sue for peace. Sindhia ceded all claims to the territory north of the Jumna, and left the blind old emperor Shah Alam once more

under British protection. The Bhonsla raja forfeited Orissa to the English, and Berar to the nizam. The freebooter, Jaswant Rao Holkar, alone remained in the field. The concluding years of Wellesley's rule were occupied with a series of operations against Holkar. Lake was repulsed at the siege of Bharatpur (Bhurltpore) (1805).

In 1804 Lord Cornwallis was sent out as governor-general a second time, with instructions to bring about peace at any price, but he died at Ghazipur before he had been ten weeks in the country. His immediate successor, Sir George Barlow, had no alternative but to carry out faithfully the orders of his employers.

Minto.—Lord Minto, governor-general from 1807 to 1813, consolidated the conquests which Wellesley had acquired. The condition of central India continued to be disturbed, but Lord Minto succeeded in preventing any violent outbreaks without himself having recourse to the sword. In his time the Indian government first opened relations with a new set of foreign powers by sending embassies to the Punjab, to Afghanistan and to Persia. Sir Charles Metcalfe was the envoy to the court of Ranjit Singh at Lahore; Mountstuart Elphinstone met the shah of Afghanistan at Peshawar; and Sir John Malcolm was despatched to Persia.

Gurkha War.—The successor of Lord Minto was Lord Moira, better known as the marquis of Hastings, who governed India for the long period of nine years, from 1814 to 1823. This period was marked by two wars of the first magnitude, the campaigns against the Gurkhas of Nepal, and the third and last Mahratta War. The Gurkhas, the present ruling race in Nepal, are Hindu immigrants who claim a Rajput origin. Their sovereignty dates only from 1767. Organized upon a sort of military and feudal basis, they soon became a terror to all their neighbours, marching east into Sikkim, west into Kumaon, and south into the Gangetic plains. In the last quarter their victims were British subjects, and nothing was left to Lord Moira but to take up arms. The campaign of 1814 was little short of disastrous. But in 1815 General Ochterlony, who commanded the army operating by way of the Sutlej, stormed one by one the hill forts which still stud the Himalayan states now under the Punjab government, and compelled the Nepal *darbar* to sue for peace. In the following year the same general advanced from Patna into the valley of Katmandu, and finally dictated the terms which had before been rejected, within a few miles of the capital. By the treaty of Segauli, which defines the English relations with Nepal to the present day, the Gurkhas withdrew on the one hand from Sikkim, and on the other from those lower ranges of the western Himalayas, which have supplied the health-giving stations of Naini Tal, Mussoorie and Simla.

Meanwhile the condition of central India was every year becoming more unsatisfactory. There a new breed of freebooters had arisen in the Pindaris, who welcomed to their ranks the outlaws of all India—Afghans, Mahrattas or Jats. Their headquarters were in Malwa, but their depredations were not confined to central India. In bands, sometimes numbering a few hundreds, sometimes many thousands, they rode out on their forays as far as the Coromandel coast. To suppress the Pindari hordes, who were supported by the sympathy, more or less open, of all the Mahratta chiefs, Lord Hastings collected the strongest British army that had been seen in India, numbering nearly 120,000 men. The Pindaris were attacked and cut to pieces.

Third Mahratta War.—In the same year (1817) as that in which the Pindaris were crushed, and almost in the same month (November), the three great Mahratta powers at Poona, Nagpur and Indore rose against the English. The peshwa, Baji Rao, had long been chafing under the terms imposed by the treaty of Bassein (1802), and the subsequent treaty of Poona (1817), which riveted yet closer the chains of dependence upon the paramount power. Elphinstone, then resident at his court, foresaw what was coming and ordered up a European regiment from Bombay. The next day the residency was burned down, and Kirkee was attacked by the whole army of the peshwa. The attack was bravely repulsed, and the peshwa immediately fled from his capital. Almost the same plot was enacted at Nagpur,

where the honour of the British name was saved by the sepoy who defended the hill of Sitabaldi against enormous odds. The army of Holkar was defeated in the following month at the pitched battle of Mehidpur. The peshwa himself surrendered, and was permitted to reside at Bithur, near Cawnpore, on a pension of £80,000 a year. His adopted son was the infamous Nana Sahib. The greater part of his dominions was ultimately incorporated in the Bombay presidency, while the nucleus of the Central Provinces was formed out of territory taken from the peshwa and the raja of Nagpur. The map of India, as thus drawn by Lord Hastings, remained substantially unchanged until the time of Lord Dalhousie.

First Burmese War.—The marquis of Hastings was succeeded by Lord Amherst, whose administration lasted for five years, from 1823 to 1828. It is known in history by two prominent events, the first Burmese War and the capture of Bharatpur. For some years past the north-east frontier had been disturbed by the restlessness of the Burmese. The successors of Alompra, after having subjugated all Burma, and overrun Assam, which was then an independent kingdom, began a series of encroachments upon British territory in Bengal. As all peaceful proposals were scornfully rejected, Lord Amherst was compelled to declare war in 1824. One expedition with gunboats proceeded up the Brahmaputra into Assam; another marched by land through Chittagong into Arakan, for the Bengal sepoy refused to go by sea; a third, and the strongest, sailed from Madras direct to the mouth of the Irrawaddy. The war was protracted over two years. At last, after the loss of about 20,000 lives and an expenditure of £14,000,000, the king of Ava consented to sign the treaty of Yandabu, by which he abandoned all claim to Assam, and ceded the provinces of Arakan and Tenasserim. He retained all the valley of the Irrawaddy, down to the sea at Rangoon. The capture of Bharatpur in central India by Lord Combermere in 1826 wiped out the repulse which Lord Lake had received before that city in January 1805. A disputed succession had necessitated British intervention. The city was taken by storm.

Bentinck.—The next governor-general was Lord William Bentinck, who had been governor of Madras twenty years earlier at the time of the mutiny of Vellore. His seven years' rule (from 1828 to 1835) forms an epoch in administrative reform. He re-

BANKIPORE, INDIA. A GREAT GRANARY BUILT IN 1780 TO BE FILLED WITH GRAIN TO GUARD AGAINST FAMINE. STAIRWAY LEADS TO TOP: GRAIN TAKEN OUT AT BOTTOM.

stored equilibrium to the finances and widened the gates by which educated Indians could enter the service of the company.

His two most memorable acts are the abolition of suttee and the suppression of the Thugs. Lord William carried the regulation in council on the 4th of December 1829, by which all who abetted suttee were declared guilty of "culpable homicide." The honour of suppressing Thuggism must be shared between Lord William and Captain Sleeman. Between 1826 and 1835, 1,562 Thugs were apprehended in different parts of British India.

Two other historical events are connected with the adminis-

tration of Lord William Bentinck. In 1833 the charter of the East India Company was renewed for twenty years, but only upon the terms that it should abandon its trade and permit Europeans to settle freely in the country. At the same time a legal or fourth member was added to the governor-general's council, who might not be a servant of the company, and a commission was appointed to revise and codify the law. Macaulay was the first legal member of council, and the first president of the law commission. In 1830 it was found necessary to take the state of Mysore under British administration, where it continued until 1881, when it was restored; and in 1834 the frantic misrule of the raja of Coorg brought on a short and sharp war. The raja was permitted to retire to Benares, and the brave and proud inhabitants of that mountainous little territory decided to place themselves under the rule of the company.

After a brief and provisional tenure by Sir Charles Metcalfe of the office of governor-general, Lord Auckland was sent out, and with him commenced a new era of war and conquest, which may be said to have lasted for twenty years.

First Afghan War.—In 1837, when the curtain rises upon the drama of British interference in Afghanistan, a usurper, Dost Mohammed Barakzai, was firmly established at Kabul. His great ambition was to recover Peshawar from the Sikhs; and when Captain Alexander Burnes arrived on a mission from Lord Auckland, with the ostensible object of opening trade, the Dost was willing to promise everything, if only he could get Peshawar. But Lord Auckland had another and more important object in view. At this time the Russians were advancing rapidly in Central Asia, and a Russian envoy was at Kabul at the same time as Burnes. The latter was unable to satisfy the demands of Dost Mohammed in the matter of Peshawar, and returned to India unsuccessful. Lord Auckland forthwith resolved upon the hazardous plan of placing a more subservient ruler upon the throne of Kabul. Shah Shuja, an exiled predecessor of Dost Mohammed, was selected for the purpose, and a British army escorted him to Afghanistan through the Bolan Pass. Kandahar surrendered, Ghazni was taken by storm, Dost Mohammed fled across the Hindu Kush, and Shah Shuja was triumphantly led into the Bala Hissar at Kabul in August 1839. During the two years that followed Afghanistan remained in the military occupation of the British. The catastrophe occurred in November 1841, when Sir Alexander Burnes was assassinated in the city of Kabul. The troops in the cantonments were then under the command of General Elphinstone (not to be confounded with the civilian Mountstuart Elphinstone), with Sir William Macnaghten as chief political adviser. Elphinstone was an old man, unequal to the responsibilities of the position. Macnaghten was treacherously murdered at an interview with the Afghan chief, Akbar Khan, eldest son of Dost Mohammed. After lingering in their cantonments for two months, the British army set off in the depth of winter to find its way back to India through the passes. When they started they numbered 4,000 fighting men, with 12,000 camp followers. A single survivor, Dr. Brydon, reached the friendly walls of Jalalabad, where General Sale was gallantly holding out. The rest perished in the defiles of Khurd Kabul and Jagdalak, either from the knives and matchlocks of the Afghans or from the effects of cold. A few prisoners, mostly women, children and officers, were considerably treated by the orders of Akbar Khan.

The punitive forces under generals Pollock and Nott converged on Kabul in September 1842. The great *bazar* was blown up with gunpowder to fix a stigma upon the city; the prisoners were recovered; and all marched back to India, leaving Dost Mohammed to take undisputed possession of his throne.

Annexation of Sind.—Lord Ellenborough, who had now superseded Lord Auckland, soon plunged into two more wars. In 1843 the Mohammedan rulers of Sind, known as the "meers" or amirs, whose only fault was that they would not surrender their independence, were crushed by Sir Charles Napier. The victory of Meeanee, in which 3,000 British troops defeated 20,000 Baluchis, is perhaps the most brilliant feat of arms in Indian history; but an honest excuse can scarcely be found for the annexa-

tion of the country. In the same year a disputed succession at Gwalior, fomented by feminine intrigue, resulted in an outbreak of the overgrown army which the Sindhia family had been allowed to maintain. Peace was restored by the battles of Maharajpur and Punniar, at the former of which Lord Ellenborough was present in person.

First Sikh War.—In 1844 Lord Ellenborough was recalled by the court of directors, and succeeded by Sir Henry (afterwards Lord) Hardinge, who had served through the Peninsular War and had lost a hand at Ligny. In 1845 the *khalsa*, or Sikh army, numbering 60,000 men with 150 guns, crossed the Sutlej and invaded British territory. Sir Hugh Gough, the commander-in-chief, together with the governor-general, hurried up to the frontier. Within three weeks four pitched battles were fought, at Mudki, Ferozeshah, Aliwal and Sobraon. The British loss on each occasion was heavy; but by the last victory the Sikhs were driven across the Sutlej, and Lahore surrendered to the British. By the terms of peace then dictated the infant son of Ranjit, Dhuleep Singh, was recognized as raja; the Jullundur Doab, or tract between the Sutlej and the Ravi, was annexed; the Sikh army was limited to a specified number; Major Henry Lawrence was appointed to be resident at Lahore; and a British force was detailed to garrison the Punjab for a period of eight years.

Dalhousie.—Lord Dalhousie succeeded Lord Hardinge, and his eight years' administration (from 1848 to 1856) was more pregnant of results than that of any governor-general since Wellesley. Though professedly a man of peace, he was compelled to fight two wars, in the Punjab and in Burma. These both ended in large acquisitions of territory, while Nagpur, Oudh and several minor states also came under British rule. But Dalhousie's own special interest lay in the advancement of the moral and material condition of the country. No branch of the administration escaped his reforming hand. He founded the public works department, to pay special attention to roads and canals. He opened the Ganges canal, still the largest work of the kind in the country, and he turned the sod of the first Indian railway. He promoted steam communication with England via the Red Sea, and introduced cheap postage and the electric telegraph.

Second Sikh War.—Lord Dalhousie had not been six months in India before the second Sikh war broke out. Two British officers were treacherously assassinated at Multan, and this outbreak of fanaticism led to a general rising. The *khalsa* army again came together, and more than once fought on even terms with the British. On the fatal field of Chillianwalla, the British lost 2,400 officers and men, besides four guns and the colours of three regiments. Before reinforcements could come out from England, with Sir Charles Napier as commander-in-chief, Lord Gough had restored his own reputation by the crowning victory of Gujrat, which absolutely destroyed the Sikh army. The Punjab henceforth became a British province, supplying a virgin field for the administrative talents of Dalhousie and the two Lawrences. Raja Dhuleep Singh received an allowance of £50,000 a year, on which he retired to Norfolk in England.

Second Burmese War.—The second Burmese war of 1852 was caused by the ill-treatment of European merchants at Rangoon, and the insolence offered to the captain of a frigate who had been sent to remonstrate. The whole valley of the Irrawaddy, from Rangoon to Prome, was occupied in a few months, and, as the king of Ava refused to treat, it was annexed, under the name of Pegu, to the provinces of Arakan and Tenasserim, which had been acquired in 1826.

Lord Dalhousie's dealings with the Indian states, though actuated by the highest motives, seem now to have proceeded upon mistaken lines. His policy of annexing each Indian state on the death of its ruler without natural heirs produced a general feeling of insecurity of tenure among the princes, and gave offence to the people of India. The first state to escheat to the British government was Satara, which had been reconstituted by Lord Hastings on the downfall of the peshwa Baji Rao in 1818. In 1853 Jhansi suffered the same fate as Satara. But the most conspicuous application of the doctrine of lapse was the case of

Nagpur. The last of the Bhonslas, a dynasty older than the British government itself, died without a son, natural or adopted, in 1853. That year also saw British administration extended to the Berars, or the assigned districts which the nizam of Hyderabad was induced to cede as a territorial guarantee for the subsidies which he perpetually kept in arrears.

Annexation of Oudh.—The annexation of Oudh was justifiable on the ground of morals, though not on that of policy. Ever since the nawab wazir, Shuja-ud-Dowlah, received back his forfeited territories from the hands of Lord Clive in 1765, the very existence of Oudh as an independent state had depended only upon the protection of British bayonets. Thus, preserved alike from foreign invasion and from domestic rebellion, the long line of subsequent nawabs had given way to neglect of public affairs and private vices. Repeated warnings were neglected, and Lord Dalhousie at last (1856) issued orders to General (afterwards Sir James) Outram, then resident at the court of Lucknow, to assume the direct administration of Oudh. The king, Wajid Ali, bowed to irresistible force, and settled down in the pleasant suburb of Garden Reach near Calcutta, where he lived in the enjoyment of a pension of £120,000 a year. Oudh was thus annexed without a blow.

The Mutiny.—Lord Dalhousie was succeeded by his friend, Lord Canning, who, at the farewell banquet in England given to him by the court of directors, uttered these prophetic words: "I wish for a peaceful term of office. But I cannot forget that in the sky of India, serene as it is, a small cloud may arise, no larger than a man's hand, but which, growing larger and larger, may at last threaten to burst and overwhelm us with ruin." In the following year the sepoys of the Bengal army mutinied, and anarchy filled the valley of the Ganges from Patna to Delhi.

The various motives assigned for the Mutiny appear inadequate. In the first place, the policy of Dalhousie was utterly distasteful to the Indian mind. Repeated annexations, the spread of education, the appearance of the steam engine and the telegraph wire, all alike revealed a consistent determination to substitute an English for an Indian civilization. The Bengal sepoys were unbalanced by a sense of their own importance; they believed it was by their prowess that the Punjab had been conquered, and all India was held quiet. The numerous dethroned princes, their heirs and their widows, were the first to take advantage of the spirit of disaffection that was abroad.

But in addition to these general causes of unrest the condition of the Indian army had long given anxiety to acute observers. During the course of its history it had broken out into mutiny at recurrent intervals, the latest occasion being the winter of 1843-1844, when there were two separate mutinies in Sind and at Ferozepur. Sir Hugh Gough and other commanders-in-chief had petitioned for the removal of India's chief arsenal from Delhi to Umballa; and Lord Dalhousie himself had protested against the reduction of the British element in the army. But all these warnings were disregarded. Moreover the outbreak was immediately provoked by an unparalleled instance of carelessness; for it is now clear that the sepoys' belief that their cartridges were greased with the fat of cows and pigs had some foundation in fact. (For the military incidents of the Mutiny see INDIAN MUTINY.)

Transfer to the Crown.—The Mutiny sealed the fate of the East India company, after a life of more than two and a half centuries. The Act for the Better Government of India (1858) finally transferred the entire administration from the company to the crown. The governor-general received the new title of viceroy. The European troops of the company, numbering about 24,000 officers and men, were amalgamated with the royal service, and the Indian navy was abolished. By the Indian Councils Act (1861) the governor-general's council and also the councils at Madras and Bombay were augmented by the addition of non-official members for legislative purposes only; and by another act passed in the same year high courts of judicature were constituted.

(ME.)

INDIA IN THE BRITISH EMPIRE

It fell to the lot of Lord Canning both to suppress the Mutiny

and to introduce the peaceful revolution that followed. He preserved his equanimity undisturbed in the darkest hours of peril, and the strict impartiality of his conduct incurred alternate praise and blame from the extremists on either side. The epithet then scornfully applied to him of "Clemency" Canning is now remembered only to his honour. On November 1, 1858, at a grand durbar held at Allahabad the royal proclamation was published which announced that the queen had assumed the government of India. This document, which has been called the Magna Charta of the Indian people, went on to explain the policy of political justice and religious toleration which it was her royal pleasure to pursue, and granted an amnesty to all except those who had directly taken part in the murder of British subjects. Peace was proclaimed throughout India on the 8th of July 1859. The suppression of the Mutiny increased the debt of India by about 40 millions sterling, and the military changes that ensued augmented the annual expenditure by about 10 millions. To grapple with this deficit, the Government reorganized the customs system, imposed an income tax and licence duty and created a state paper currency. The penal code, originally drawn up by Macaulay in 1837, passed into law in 1860, with codes of civil and criminal procedure.

Lord Canning left India in March 1862, and died before he had been a month in England. His successor, Lord Elgin, only lived till November 1863, when he too fell a victim to the excessive work of the governor-generalship, dying at the Himalayan station of Dharmasala, where he lies buried. He was succeeded by Sir John Lawrence, the saviour of the Punjab. The chief incidents of his administration were the Bhutan war and the terrible Orissa famine of 1866. Lord Mayo, who succeeded him in 1869, carried on the permanent British policy of moral and material progress with a special degree of personal energy. While engaged in exploring with his own eyes the furthest corners of the empire, he fell by the hand of an assassin in the convict settlement of the Andaman islands in 1872. His successor was Lord Northbrook, whose ability showed itself chiefly in the department of finance. During his administration a famine in Lower Bengal in 1874 was successfully obviated by government relief and public works, though at an enormous cost; the Gaekwar of Baroda was dethroned in 1875 for misgovernment and disloyalty, while his dominions were continued to a nominated child of the family; and the prince of Wales (Edward VII.) visited the country in the cold season of 1875-1876. Lord Lytton followed Lord Northbrook in 1876. On the 1st of January 1877 Queen Victoria was proclaimed empress of India at a durbar of great magnificence, held on the historic "Ridge" overlooking the Moghul capital Delhi.

Second Afghan War.—In the autumn of 1878 the affairs of Afghanistan again forced themselves into notice. Shere Ali, the amir, who had been hospitably entertained by Lord Mayo, was found to be favouring Russian intrigues. A British envoy was refused admittance to the country, while a Russian mission was received with honour. This led to a declaration of war. British armies advanced by three routes—the Khyber, the Kurram and the Bolan—and without much opposition occupied the inner entrances of the passes. Shere Ali fled to Afghan Turkistan, and there died. A treaty was entered into with his son, Yakub Khan, at Gandamak, by which the British frontier was advanced to the crests or farther sides of the passes and a British officer was admitted to reside at Kabul. Within a few months the British resident, Sir Louis Cavagnari, was treacherously attacked and massacred, together with his escort, and an advance became necessary. Yakub Khan abdicated, and was deported to India, while Kabul was occupied in force. Shortly afterwards a British brigade was defeated at Maiwand by the Herati army of Ayub Khan, a defeat promptly and completely retrieved by the brilliant march of General Sir Frederick Roberts from Kabul to Kandahar, and by the total rout of Ayub Khan's army on the 1st of September 1880. Abdur Rahman Khan, the eldest male representative of the stock of Dost Mohammed, was then recognized as amir of Kabul.

Lord Ripon.—While these operations were in progress, Lord Ripon was sent out to India by the Liberal ministry of 1880 for the purpose of reversing Lord Lytton's policy in Afghanistan, and of introducing a more sympathetic system into the administration

of India. The disaster at Maiwand, and the Russian advance east of the Caspian, prevented the proposed withdrawal from Quetta; but Kandahar was evacuated, Abdur Rahman was left in complete control of his country and was given an annual subsidy of twelve lakhs of rupees in 1883. In the second purpose of his administration Lord Ripon laid the foundation of a system of local self-government, on which the superstructure was long delayed. A relatively minor measure known as the Ilbert Bill, which proposed to subject European offenders to trial for certain offences by native magistrates, aroused a storm of indignation amongst the European community which finally resulted in the bill being modified; but it also set a fashion in political agitation, which was to bear bitter fruit. Lord Ripon's good intentions and personal sympathy were recognized by the Indians, and on leaving Bombay he received a great ovation.

After the arrival of Lord Dufferin as governor-general the incident known as the Panjdeh scare brought Britain to the verge of war with Russia. During the preceding decades Russia had gradually advanced her power from the Caspian across the Turkoman steppes to the border of Afghanistan, and it was found necessary to appoint a joint Anglo-Russian commission to delimit the Afghan frontier. In March 1885, while the commission was at work, a Russian general attacked and routed the Afghan force holding the bridge across the river Kushk, and the incident might possibly have resulted in war between Britain and Russia but for the slight importance that Abdur Rahman attributed to what he termed a border scuffle.

The incident, however, led to military measures being taken by the government of Lord Dufferin, which had far-reaching effects on Indian finance. The total strength of the army was raised by 10,000 British and 20,000 Indian troops, at an annual cost of about two millions sterling; and the frontier post of Quetta, in the neighbourhood of Kandahar, was connected with the Indian railway system by a line that involved very expensive tunnelling.

Imperial Service Troops.—The Panjdeh incident was likewise the cause of the establishment of Imperial Service troops in India. Many of the leading Indian princes agreed to set up a small military force in their States, to be at the disposal of the British government, to be commanded by state officers, but drilled, disciplined and armed under the supervision of British officers and on British lines, the government finding the necessary supervising officer, arms and organization. The Imperial Service troops, as they are called, amounted in 1928 to some 20,000 cavalry, infantry and transport, whose efficiency was put to the highest test during the Great War. Later in the same year (1885) occurred the third Burmese war, which ended in the annexation of Upper Burma. For the causes of the dispute with King Thebaw, and a description of the military operations which ensued before the country was finally pacified, see BURMA. Between the years 1885 and 1895 there were delimited at various times by joint commissions the Russo-Afghan frontier between the Oxus and Sarakhs on the Persian frontier, the Russo-Afghan frontier from Lake Victoria to the frontier of China and the Afghan-Indian frontier from the Kunar river to a point in the neighbourhood of the Nawa Kotal.

About the same time in the extreme north the post of British resident in Gilgit was re-established, and the supremacy of Kashmir over the adjoining petty chiefships of Hunza-Nagar was enforced (1891-1892). In 1893 the frontiers of Afghanistan and British India were defined by a joint agreement between the two governments, known as the Durand agreement. There followed an extension of British defensive posts into tribal territory, which aroused the alarm of the local clans. The Waziris and Swatis successively rose in arms, in June and July 1897, and their example was followed by the Mohmands. Finally, in August the powerful Afridi tribe joined the combination and closed the Khyber Pass, which runs through their territory, and which was held by them, on conditions, in trust for the government of India. This led to the Tirah campaign, which proved very costly both in men and money.

Lord Curzon's Reforms.—When Lord Curzon became viceroy in 1898, he reversed the frontier policy, which had given rise to the Tirah campaign, withdrew outlying garrisons in tribal

country, substituted for them tribal militia, and created the new North-West Frontier province, for the purpose of introducing consistency of policy and firmness of control upon that disturbed border. This was only one phase of his boundless activity. In almost every branch of the administration he introduced far-reaching reform. He reorganized the systems of education and police, laid down a comprehensive scheme of irrigation, improved the leave rules and the excessive report-writing of the civil service, encouraged the princes by the formation of the Imperial Cadet Corps and exhibited a practical zeal for justice between Indian and Englishman, which at times imperilled his personal popularity. His term of office was also notable for the coronation durbar at Delhi in January 1903, the expedition to Lhasa in 1904, which first unveiled that forbidden city to European gaze, and the partition of the overgrown province of Bengal in 1905. In December 1904 Lord Curzon entered upon a second term of office, which was unfortunately marred by a controversy with Lord Kitchener, the commander-in-chief, as to the position of the military member of council. Lord Curzon, finding himself at variance with the secretary of state, resigned before the end of the first year, and was succeeded by Lord Minto.

Lord Minto.—The new viceroy, who might have expected a tranquil time after the energetic reforms of his predecessor, soon found himself face to face with grave unrest, the outcome of the growing nationalist movement, and of the pressure of a western civilization upon a people with an increasing pride in their own ancient culture. Ever since 1885 the small class of Indians with an English education had been claiming for themselves a larger share in the administration, and had organized a political party under the name of the National Congress, which held annual meetings at Christmas in one or other of the large cities of the peninsula. This class also exercised a wide influence through the press, printed both in the vernacular languages and in English, especially among young students. There is no doubt too that the adoption of Western civilization by the Japanese and their victorious war with Russia set in motion a current through all the peoples of the East. The occasion though not the cause of trouble arose from the partition of Bengal, which was represented by Bengali agitators as an insult to their mother country. Beneath the constitutional agitation lay a stratum of bitter economic discontent. The schools and colleges had been pouring out masses of young men, imperfectly educated, underfed, for whom no place existed in the public services or the industrial system of the country, and whose misery generated a fierce hostility to existing order. From this soil sprang the *swadeshi* movement for the boy-

A DINGHY, THE NATIVE PASSENGER AND LIVING BOAT OF INDIA

cott of English goods, the most seditious speeches and writings and conspiracies for the assassination of officials.

At first the government attempted to quell the disaffection by means of the ordinary law, with fair success outside Bengal; but there, owing to the secret ramifications of revolutionary activity, it was found necessary to adopt special measures. Recourse was had to a regulation of the year 1818, by which persons may be imprisoned or "deported" without reason assigned; and three acts of the legislature were passed for dealing more directly with the prevalent classes of crime: (1) an Explosives Act, containing pro-

visions similar to those in force in England; (2) a Prevention of Seditious Meetings Act, which could only be applied specially by proclamation; and (3) a Criminal Law Amendment Act, of which the two chief provisions were a magisterial inquiry in private (similar to the Scotch procedure) and a trial before three judges of the High Court without a jury.

While the law was thus strictly enforced, important acts of conciliation and measures of reform were carried out simultaneously, in concert between Lord Minto and Lord Morley, then secretary of state for India. In 1907 two Indians, a Hindu and a Mohammedan, were appointed to the secretary of state's council. Occasion was taken of the fiftieth anniversary of the assumption by the crown of the government of India to address a message (on November 2, 1908) by the king-emperor to the princes and peoples, reviewing in stately language the later development, and containing these memorable words:—

From the first, the principle of representative institutions began to be gradually introduced, and the time has come when, in the judgment of my viceroy and governor-general and others of my counsellors, that principle may be prudently extended. Important classes among you, representing ideas that have been fostered and encouraged by British rule claim equality of citizenship, and a greater share in legislation and government. The politic satisfaction of such a claim will strengthen, not impair, existing authority and power. Administration will be all the more efficient if the officers who conduct it have greater opportunities of regular contact with those whom it affects and with those who influence and reflect common opinion about it.

The Morley-Minto Reforms.—The policy here adumbrated was translated by parliament into the India Councils Act, 1909, of which the main object was to enlarge the Legislative Councils and make them more fully representative, introduce the elective principle, give greater powers of discussion and of obtaining information from the executive. In each Council the nominated members comprised: (1) a substantial *bloc* of officials, the *bloc* in the Imperial Legislative Council being large enough to secure, together with the members of the Executive Council, an absolute majority; (2) non-officials nominated to represent classes or interests which would otherwise be unrepresented or inadequately represented. The number of elected members was too few to admit of any system of territorial constituencies and direct voting. Special constituencies therefore were formed, such as universities, chambers of commerce, groups of municipalities and district boards, and also for Mohammedans as a separate class or community. The councils were empowered to discuss and move resolutions on the annual budget and in like manner to raise discussions by resolution on matters of general public interest. But they did not vote the budget, and resolutions operated only as recommendations which were not binding on the Government.

The Act increased the number of members of the executive councils of Madras and Bombay from two to a maximum of four, thereby providing a seat for an Indian or two Indian members; it also authorized the creation of an executive council in any province having a lieutenant-governor. The policy of associating Indians with the executive government thus affirmed as regards to provinces, was given effect to in the Government of India by the appointment first of Mr. S. P. (afterwards Lord) Sinha, and then of Sir Ali Imam as Law Member of the Governor-General's executive council. The first elections under the new scheme took place in December 1909, and aroused widespread interest. The new council of the Governor-General met in January 1910.

Lord Hardinge.—In the spring of 1910 the appointment of Lord Kitchener to succeed Lord Minto as Viceroy seemed probable. Fate reserved Lord Kitchener for other tasks, and the choice fell on Sir Charles Hardinge, permanent Under-Secretary for Foreign Affairs and formerly ambassador to St. Petersburg, who was raised to the peerage as Lord Hardinge of Penshurst. His viceroyalty (Nov. 1910–March 1916) was strenuous and eventful. The earlier years were marked by the visit of King George V. and Queen Mary to India, the selection of Delhi as the site of the future capital of the Indian Empire, the revision of the "partition" of Bengal and the nefarious attempts of anarchists to compass the deaths of the Viceroy and his wife on the occasion of their state entry into Delhi. The closing years saw India in the throes of the World War, when the popularity of the Viceroy

and his personal influence and friendship with the ruling Princes had much to do with the magnificent response of India to the call of the Empire.

Lord Minto had predicted that the conciliatory measures embodied in and associated with these changes would clear the political atmosphere. He prophesied rightly. On Jan. 5, 1911, a deputation from the Indian National Congress presented an address to the new Viceroy expressing deep and heartfelt loyalty to the Crown and appreciation of the reforms which "had done much to bring about a better understanding between the Government and the people." As the enlarged councils settled down to their work, even the advanced party found, for a time at least, a healthy outlet for their energies. As consultative and critical bodies the reformed councils exercised a real and growing influence and were an educative force. They formed, directed, and developed public opinion in political matters. They acted as a restraint upon the autocratic tendencies of the Executive and made it more responsive to popular demands, and they strengthened its hands when it had to sustain Indian interests against the interests of Great Britain or of the self-governing Dominions.

The Royal Visit.—The royal visit in the winter of 1911 was a remarkable triumph. The presence of the King-Emperor and his Consort in India touched the imagination and fired the innate loyalty of the people. The Delhi ceremonies drew vast crowds eager to see and salute the sovereign. When a visit to Calcutta followed, the welcome given by the populace of that city was even more enthusiastic and unrestrained. On Dec. 12, 1911, in a great arena outside Delhi specially prepared for the occasion, the King held a coronation durbār at which he received in person the homage of the great officers of state and the ruling princes and chiefs of the Indian Empire. Largesse and "boons" of various kinds were granted, and an announcement made of great political moment. The seat of the Government of India was to be transferred from Calcutta to Delhi; Eastern Bengal was reunited to Bengal and the enlarged province given a Governor in Council; Behar, Orissa and Chota Nagpur, tracts which are loosely connected with Bengal proper, were made a Lieutenant-Governorship in Council; and Assam was re-formed into a chief commissionership. The secret had been well kept, and the surprise was complete. The scheme, though open to obvious objections, was ingenious and cleverly balanced. A reasoned exposition of its object is contained in a despatch, dated Aug. 25, 1911, from the Government of India to the Secretary of State, submitting the proposed changes for the home Government's approval in advance of the King's visit.

Prosperity and Progress.—The period was one of much material prosperity, and it was possible to make large grants for the advance of popular education and for sanitary reforms that had long seemed unattainable. The funds were in considerable measure found from the fanciful prices paid for opium by the China market in view of the steps that were being taken to reduce and ultimately extinguish the trade in the drug from India. A royal commission enquired into the public services and recommended a larger proportion of Indians in the higher ranks. A Legislative Council was established in the Central Provinces. The position of Indians in the Dominions and Colonies began to attract criticism; serious dissatisfaction being in particular aroused by the treatment of indentured labour in Fiji and elsewhere, and by the disabilities imposed on Indian residents in South Africa and Canada. In 1911 the Indian Government prohibited the future emigration of indentured labourers to Natal; and in the following year there was widespread unrest among the Indians domiciled in the Union. Speaking at Madras in Nov. 1913, Lord Hardinge attacked the "invidious and unjust laws" against which the Indians were protesting, and pressed for an independent inquiry into the whole matter. This was subsequently conceded, and peace was reached for a time by the Union Government passing its Indian Relief Act, 1914. With regard to Canada the Indian grievances were less easy of settlement, and Lord Hardinge could only advise a policy of reciprocity, which could be made effective without direct retaliation.

Revolutionary Crime.—Under the surface of all this peace-

ful progress the new and sinister feature in Indian life which had emerged in Lord Minto's time was gaining in intensity. Secret societies, composed chiefly of young men belonging to respectable families, sprang up in many districts of Bengal, having for their object the deliverance of India from the foreign yoke. This they sought to compass by assassination and terrorism. The art of bomb-making was imported from Europe. Revolutionary literature and the use of pistols and explosives were sedulously studied, and a series of anarchical crimes occurred from 1907-9. On Dec. 23, 1912, as the Viceroy was making his first state entry into Delhi, a bomb was thrown and exploded in the *howdah* of the elephant on which he and Lady Hardinge were riding, severely wounding him and killing an attendant. In 1914 and 1915 revolutionary activities became more daring, with the assistance of German agents in America and the Dutch East Indies; but the vigorous use of the special powers provided by the Defence of India Act broke up the movement for the time being and restored order. The organisation of the revolutionary societies, their inter-connection and propaganda methods, their success in corrupting the educated youth of the country, are minutely described in the report of the Sedition Committee (1918) over which Mr. Justice Rowlatt presided.

THE WORLD WAR

On the outbreak of the World War in Aug. 1914, the response made by India to the needs of the Empire was signal testimony of her pride in the British connection. The political leaders suspended their controversies with the Government. The martial classes eagerly responded to the call to arms. From the rulers of the Indian states lavish offers of help poured in. They were recounted in the Viceroy's telegram to the Secretary of State, dated Sept. 7, 1914, which was read in both Houses of Parliament and circulated throughout the Empire. Its effect on popular feeling was immense.

With this confidence and enthusiasm were mingled some alarm and bewilderment; and the Punjab in particular was disturbed for some months by murders, dacoities and robberies, and the reckless use of arms and explosives.

But India as a whole was calm, and the Government was able to denude itself freely of its military resources to meet the demands of the home Government for troops and supplies. Most of the British troops, the flower of the Indian army, the best of the artillery, and large quantities of ammunition were despatched to France and other theatres of war. In Sept. 1914 a force of 70,000 men was sent to France. By the end of 1915 India's contribution amounted to nearly 80,000 British and 210,000 Indian officers and men. At one time the original British garrison was reduced to only 15,000 men.

The entrance of Turkey into the War placed Indian Mohammedans in a difficult position; but they loyally rallied to the side of the Crown. Against a few prominent agitators only was it necessary to take action. The premier Mohammedan prince, the Nizam of Hyderabad, and the Begum of Bhopal, in addresses to their co-religionists, effectively stated the British case. These addresses and a declaration by the Government of India as to its attitude towards Islam in general and the Holy Places in particular served greatly to maintain tranquillity.

Lord Chelmsford.—Lord Chelmsford, the new Viceroy, assumed office on April 4, 1916. Previously Governor of Queensland and of New South Wales, at the time of his appointment he had been serving as an officer with a territorial battalion in India; and he was cast at once into one of the most difficult periods of British-Indian history. In the very first year of his administration the political peace enjoyed by his predecessor came to an end. Mrs. Annie Besant and Mr. B. G. Tilak raised the home-rule flag in Madras and Bombay respectively. In Oct. 1916, a group of elected Indian members of the Imperial Legislative Council submitted a memorandum on proposed reforms to the Government of India. It propounded a scheme which, while retaining irremovable executives responsible to Parliament and the Secretary of State, would have subjected them in legislation, finance and administration, to the orders of a legislative body in which elected

members would be predominant.

At meetings held in Lucknow in Dec. 1916 the National Congress and the Muslim League agreed upon a scheme of reforms as the irreducible minimum with which the National party would be content; and made a compact guaranteeing to Mohammedans a proportion of seats in the future Legislative Councils in excess of the number they could hope otherwise to win. Following the Lucknow conferences an energetic Home Rule campaign was opened in all provinces. The whole problem, however, had already been referred to the British Cabinet; for before the close of 1916 Lord Chelmsford's government had submitted to the Secretary of State a considered scheme of reforms, and asked for an authoritative declaration of policy. Was the goal for the Indian peoples to be responsible government? If so, by what stages and steps should it be reached? The questions raised were large and delicate. The Cabinet was preoccupied by the War. In July 1917 the Secretary of State Mr. (Sir) Austen Chamberlain, resigned on the report of the Mesopotamian Commission.

Declaration of Aug. 20, 1917.—It fell to his successor, Mr. E. S. Montagu, to announce on Aug. 20, 1917, in the House of Commons, the Indian policy of the government:

The policy of H.M. Government is that of increasing the association of Indians in every branch of the administration and the gradual development of self-governing institutions with a view to the progressive realisation of responsible government in India as an integral part of the British Empire. . . . Progress in this policy can only be achieved by successive stages. The British Government and the Government of India, on whom the responsibility lies for the welfare and advancement of the Indian peoples, must be the judges of the time and measure of each advance, and they must be guided by the co-operation received from those upon whom new opportunities of service will thus be conferred and by the extent to which it is found that confidence can be reposed on their sense of responsibility.

In the course of the winter Mr. Montagu visited India, and a joint report, dated April 22, 1918, by himself and the Viceroy was drawn up before he left.

War Conference of 1918.—The Montagu-Chelmsford report was nearing completion when attention was recalled to the pressing realities of the War. In the Near East, German troops had penetrated the Caucasus and Turks were invading Persia. With the collapse of Russia, the opening up of a road to Afghanistan and thence to India seemed possible. In a telegram (April 2, 1918), the Prime Minister made an appeal to the Government and people of India to redouble their efforts and prevent German tyranny from "spreading to the East and engulfing the world."

Lord Chelmsford's response was to convene a War conference at Delhi, to which many ruling princes and representatives of all provinces of every shade of opinion were invited. The conference heartily and loyally responded to the appeal, and agreed upon a programme of measures of no small value. In the five months preceding the Armistice 200,000 men were recruited, and had the War gone on this number would have been greatly increased. In the spring of 1917 the Legislative Council had accepted the Government's proposal to make a free gift of £100,000,000 to the home Government towards the expenses of the War. This was in addition to the obligation the Indian Government had undertaken of bearing the normal charges of all troops on the Indian establishment sent overseas. The part borne by India in the War and the sacrifices made by her people for the common cause are represented by an addition of over 230 crores of rupees (£153,000,000) to her debt, the sending overseas of 800,000 combatants and 400,000 non-combatants, and the furnishing of foodstuffs and other supplies at the cost of much privation among the poorer classes.

Renewal of Unrest.—The Armistice in Nov. 1918 was the signal for general rejoicings but ushered in a season of political strife and agitation unfavourable for the peaceful introduction of the new constitution. Over what is generally known as the Rowlatt bills, a controversy arose, which was fated to overshadow and prejudice the constitutional question by the passions which it kindled and the bitterness which it imported into the relations of the people and the Government. The report of the Sedition Committee, over which Mr. Justice Rowlatt presided, had provided impressive evidence of the existence of a revolutionary

and anarchical conspiracy in Bengal and elsewhere and the ineffectiveness of the ordinary criminal law to deal with it. The Committee proposed to endow the Governor-General in Council with emergency powers, to be used only in specified areas, and only after a notification declaring the existence of a state of affairs in those areas which demanded emergency measures. Those measures included: (a) the trial of seditious crime by three judges of the highest status, without juries or assessors who were liable to be affected by public discussion or deliberate terrorism; and (b) the investing of a provincial Government with certain limited powers of internment. In Jan. 1919 the publication of the draft bills embodying the Committee's proposals was followed by a violent campaign by the Nationalist press and Nationalist politicians. They were represented as an attack upon the popular liberties, a monstrous engine of tyranny and oppression, the forerunner of a policy of reaction and an unmerited slur upon the loyalty and law-abidingness of the Indian people.

Gandhi.—While the bills were before the Legislative Assembly, M. K. Gandhi, a well-known social and religious reformer, revered in the Bombay Presidency as an ascetic and holy man, initiated a passive resistance movement. *Satyagraha*, as he termed it, means insistence on truth and a reliance on soul force. On the Rowlatt bills receiving the Viceroy's assent, Gandhi announced a day of general mourning and cessation of business. A wave of excitement passed over the Punjab. Violent disturbances broke out in Lahore, Amritsar and other centres. Disorder assumed the character of open rebellion, definitely anti-government and anti-British, communications were cut, and the civil authority was only maintained by military force. Martial law was proclaimed in Amritsar on April 14, was extended subsequently to other districts and was not finally withdrawn from every part of the Province until June. In Bombay the news of Gandhi's arrest at Delhi was the occasion of an immediate outbreak of disorder in Ahmadabad, the capital of Guzerat, and in neighbouring towns. The military had to be called in, but not before numerous acts of incendiarism and violence and some loss of life had occurred.

Amritsar.—On April 13 "the tragedy of Amritsar" occurred. In that city banks and other buildings had been pillaged and burnt and Europeans murdered. The civil officers, finding themselves powerless to cope with the mobs in possession of the city, called upon the military to restore order. Brigadier-General Dyer, the officer commanding, deemed it necessary in the course of his operations to disperse forcibly an unlawful assembly held in the Jallianwala Bagh. Nearly 400 persons were killed by the fire of his troops, and probably thrice that number wounded. His action aroused intense indignation among Indians of all shades of political opinion, and led to the appointment towards the end of the year of the Hunter Committee to inquire into the disturbances which had arisen in consequence of the Rowlatt legislation. General Dyer's action was condemned by this committee, and it was decided by the authorities that he should receive no further employment in India. After a warm debate in the House of Commons (July 8, 1920), this action was approved by 230 votes to 129, but the House of Lords, on July 20, by 129 votes to 86, passed a motion "deploring" the treatment of General Dyer as "unjust" and as "establishing a precedent dangerous to the preservation of order in the face of rebellion."

The Third Afghan War.—Relations with Afghanistan had been uniformly good ever since the Amir Habibullah's visit to Lord Minto in 1908. The Amir was delighted with his reception, and let it be known that his friendship with the British Government had been immensely strengthened. During the World War he was staunch; but on Feb. 20, 1919, he was murdered, and his son Amanullah ascended the throne. The succession was disliked by powerful factions in the state; and in his difficulties the new Amir lent an eager ear to the distorted reports of the disturbed state of the Punjab, which found their way to Afghanistan. He concluded that an invasion of India might prove a solution of his domestic differences, appealing as it would to the religious fanaticism of his Mohammedan subjects, deeply stirred by the humiliation and defeat of Turkey and by the British conquest of Mesopotamia. Aggressive movements of his troops in

the Khyber were countered by the rapid mobilisation of the army in India early in May, the occupation of the Afghan advanced base at Dacca and the bombing by aeroplanes of Kabul and Jalālābād. By the middle of May the Afghans asked for a cessation of hostilities, and in June the Amir accepted an armistice. On Aug. 8 a treaty of peace was signed at Rawalpindi, under which the Amir lost his subsidy and the privilege of importing arms through India. A separate letter officially recognised the freedom of Afghanistan from foreign control.

Waziristan.—The Rawalpindi Treaty did not end the troubles on the frontier. The independent tribes of Wazirs and Mahsuds, who occupy a large block of country south of the Khyber line between Afghanistan and the British districts to the east, had risen in May at the instigation of the Afghans and raided the adjoining British districts. The Indian Government determined to undertake the permanent pacification of the country, a serious undertaking, as the tribes could place some 30,000 well-armed men in the field. The Wazirs in the Tochi Valley were soon subdued, but the Mahsuds fought with dogged obstinacy and great skill. There were two considerable encounters (on Dec. 21, 1919, and Jan. 14, 1920) with heavy British casualties. In the end the Mahsuds accepted the terms imposed upon them, and the military operations closed on May 7, 1920.

In Dec. 1919 the Montagu-Chelmsford scheme of constitutional reform became law by the passing of the Government of India (Amendment) Act. The King's proclamation of Dec. 23 dwelt in eloquent and arresting language on the political advancement conferred upon the Indian peoples, and the Duke of Connaught, in opening the new legislatures a year later, made an earnest appeal for a fresh start and a new spirit. Unfortunately by this time Gandhi and his followers had burned their boats.

Non-co-operation.—The publication in 1920 of the report of the committee of enquiry into the Punjab disturbances, and of the correspondence between the Government of India and the Secretary of State regarding its findings, and the subsequent debates in Parliament renewed the bitterness and indignation which the Amritsar proceedings had aroused in India. About the same time the terms of the Sèvres Treaty became known to Indian Mohammedans and added flame to the "Khilāfat" agitation, which the pro-Turk section of that community had been vigorously fomenting. In August Gandhi proclaimed in a letter to the Viceroy his adoption of non-co-operation as a remedy against a Government for which he retained "neither respect nor affection" on account of its "unscrupulous, immoral and unjust" action in the matter of the Caliphate and its failure to punish adequately the officials responsible for "the wanton cruelty and inhumanity" with which the disorders in the Punjab were suppressed.

On April 2, 1921, Lord Chelmsford laid down the office of viceroy and was promoted viscount. No viceroy had been more tried by circumstances beyond his control, and no viceroy had shown more steadfast courage or devotion to the ideals of his great office. The era will be a landmark in the history of modern India. It saw India started on the road to self-government and admitted on equal terms to a partnership in the British Empire.

MODERN TIMES

Lord Reading.—Arriving in April 1921, the Earl of Reading brought to the office of Governor-General a prestige, as a former Lord Chief Justice of England, not exceeded by that of any of his forerunners. The task which confronted him required all his courage and experience. Though the actual machinery of the new constitution had begun its work with relative smoothness, the country was seething with an excitement for which the political changes were merely a pretext. A moderate section of Indian leaders commanded the Councils and furnished ministers to the provincial Governments. But they owed their position to the boycott of the whole scheme by the extremist politicians, whether Hindus or Muslims, who had taken no part in the elections of the previous winter, and now held no place in the Councils or the Ministries. The real battle of India's future was being fought outside the domain of constitutional Government.

Gandhi, who had been appointed virtual dictator of the nation-

alist forces at the National Congress of Christmas 1920, was sweeping the country with his cry of non-violent non-co-operation. India would then be worthy of complete Home Rule, and a date (at first Sept. 30, 1921, but subsequently extended on several occasions) was actually prophesied for the disappearance of the British Government. The Treaty of Sèvres was attacked as a device of England to humiliate her former friend and ally; and a movement of protest was engineered by the Khilāfat party, so called from their claim that the temporalities of the Sultan, as Khalifa of Islam, should be restored. It was in a struggle against this combination of forces that the first three years of Lord Reading's government were mainly spent.

The Moplah Rising.—In Aug. 1921 the most serious of many unpardonable deeds of violence broke out. The Malabar country in Madras is occupied by 2,000,000 Hindus and about 1,000,000 Moplahs, an ignorant Mohammedan peasantry of mixed Arab and Indian descent with an evil reputation for outbreaks of fanaticism. Among the latter the Khilāfat excitement flared into open rebellion. Railway and telegraph lines were cut, roads blocked, Government offices burned and a Moplah king proclaimed. The few Europeans who failed to escape from the district were brutally murdered, and then the Moplahs turned upon their inoffensive Hindu neighbours. They burned villages, sacked temples, outraged women, massacred and attempted wholesale the forcible conversion of the Hindus to Islam. Working through very difficult country, a strong military force ultimately crushed the rising in October. Gandhi and his lieutenants professed to belittle the outbreak, but it soon became apparent how gravely the Moplah atrocities rankled in the minds of the ordinary Hindus.

Visit of the Prince of Wales.—On Nov. 17, 1921 H.R.H. the Prince of Wales landed at Bombay for a visit to India which had been postponed in the preceding year. Efforts, partly successful, but frequently defeated by the Prince's arresting popularity, were made to boycott the public ceremonials arranged in his honour; yet the tour was courageously carried through. He rapidly traversed British India, carried through a heavy tale of ceremonies and interviews, visited several of the leading Indian States, as well as Nepal, inspected the northwest frontier, attended the Kadir Cup (pig-sticking meet) near Meerut, and finally left for England from Karachi in March.

During 1921 Gandhi had prepared a scheme of mass civil disobedience, both aggressive and defensive, and was on the eve of launching it, when on Feb. 4, 1922, another hideous outrage occurred. At the Chauri Chaura village, in the east of the United Provinces, 21 policemen and village watchmen were set upon by a mob of "volunteers" and excited peasants and battered to death or burned alive. Gandhi at once suspended his orders for civil disobedience, issued a new "constructive programme" which threw his followers into confusion, but he was at last arrested on March 10, 1922. Put on trial at Ahmadabad on three charges of spreading disaffection and instigating the overthrow of the Government, he pleaded guilty and was sentenced to six years' simple imprisonment. His trial produced no popular excitement. It was overshadowed by the resignation by E. S. Montagu of his office as Secretary of State, as a sequel to his having published, without Cabinet approval, a despatch from Lord Reading's Government, in which His Majesty's Government was urged, in deference to Mohammedan sentiment in India, to revise the Treaty of Sèvres.

Unrest in the Punjab.—The spirit of non-co-operation, definitely on the wane elsewhere, was now penetrating the slow-moving Punjab, and the doctrine of non-violent obstruction to authority was bearing strange fruit on unlikely soil. For some years there had been a reforming movement among the Sikhs, directed at recovering a number of scattered temples of their religion from hereditary incumbents (Mahants) and employing their revenues for the spiritual service of the people generally. The puritan reforming section (Akalis) had got into the habit of taking the law into their own hands, and ejecting by violence the Mahants of whom they disapproved. The latter appealed to the courts, or engaged armed retainers to defend their property. In either case it was necessary for the Government to intervene; and it suited the employers of the Akali bands, adherents of the non-co-opera-

tion movement, to distort this intervention into hostility against the Sikh religion. All attempts by the Government to bring the Akali fervour into orderly channels were frustrated, and in 1922 the Akalis established such a reign of terror that military assistance had to be supplied to the police.

Extremists in the Councils.—At the end of 1923 came the second general election. A strong section of the Congress Party, adopting the label of Swaraj (Home Rule), broke away from Gandhi's programme of boycott and put up a mass of candidates for the councils. They secured nearly half the elected seats in the Central Assembly; and in at least two of the provinces they commanded the provincial councils. Their discipline was good, and they had entered the legislatures with the avowed object of "uniform, continuous and consistent obstruction with a view to make Government through the Assembly and the Councils impossible." In the central legislature, they concentrated on demanding that the grant of full responsible government should be expedited. When this was not endorsed by the Government, they retaliated, in coalition with a sufficient number of members of the other parties, by rejecting the Finance bill for the year, with the result that the Viceroy had to use his emergency powers and certify the necessary expenditure of the administration. The episode, however, and the subsequent conduct of the Nationalist Coalition during the remainder of the session, established them in the role of a constitutional opposition.

Lord Birkenhead on the Constitution.—In the summer of 1925, Lord Reading accepted an invitation from the Secretary of State for India (now the Earl of Birkenhead) to visit England for the purpose of personal discussion; the Governor of Bengal, Lord Lytton, officiating as Viceroy in his absence. This was the first exercise of a new Act enabling viceroys and provincial governors to obtain leave during their term of office. It was obviously desirable to announce a line of policy in answer to the protestations of the Nationalists that the 10-year period of experiment should be curtailed, and that the British Parliament ought not to impose its judgment as to the fitness of India for self-government. On July 10 accordingly Lord Birkenhead made a careful statement in the House of Lords, reviewed the working of the Reform Act of 1919, and emphasised the lack of co-operation and the actual hostility displayed by a section of the Indian leaders. He expressed his willingness to consider any practical scheme of advance on which Indians could agree, and he did not close the door to an antedating of the statutory inquiry due in 1929, if Indian leaders gave evidence of a sincere and genuine desire to work the present machinery. Fortunately there had been steady advance in agricultural prosperity. A short monsoon in 1920 necessitated considerable famine-relief operations in the succeeding year; but thenceforward a series of remarkably good harvests lowered prices and restored the contentment of the masses. The epoch of economic distress in 1920-21 had affected the manufacturing classes even more than the patient agriculturists. Labour trouble came to the front as never before, 1921 witnessing no fewer than 400 strikes of varying magnitude, and legislative measures of a new type began to appear on the statute book.

An amended Factory Act in 1922 prescribed a 60-hour week and raised the minimum age of child workers from nine to 12. A Mines Act in 1923 dealt with the employment of women and children below ground, restricted the hours of adult labour to 60 above ground and 54 below, and enacted a weekly day of rest. The first Workmen's Compensation Act came into force in 1924, and measures were undertaken for the regulation of trade unions and the settlement of industrial disputes. Besides these legislative measures, a quieter process was at work in the steady improvement of the depressing housing conditions in the large labour centres, such as Calcutta, Bombay and Cawnpore.

In the social organization of India change was slowly moving. The non-Brahmans of Madras struck against Brahman domination, and seized power in the new provincial legislature. The lowest strata of outcasts or "untouchables" showed signs of organizing for their protection and betterment, and Gandhi led a vigorous, if not a wholly popular, mission for their uplift. Some flutterings of a feminist movement were perceptible. An accomplished In-

dian lady, the poetess, Mrs. Sarojini Naidu, occupied the chair of the National Congress of 1925. Numerous ladies of the classes which formerly prided themselves on their seclusion are now to be met on political and other platforms, and some little progress is being made towards the recognition of the re-marriage of Hindu widows. Social progress, however, lags far behind political aspirations.

Anarchical Crime.—The inroads on the tranquillity of the country which ensued on extremist agitation unfortunately provided cover for a revival in Bengal of revolutionary crime on the familiar lines:—dacoities, looting, assassination and the intimidation of witnesses. Conspiracies multiplied in 1923; and early in 1924 an inoffensive Englishman was shot in the streets of Calcutta in mistake for a police official; the Bengal Provincial Conference in the following July passing a resolution laudatory of the "noble self-sacrifice" of the murderer. In Oct. 1924 came a special ordinance for dealing, by exceptional procedure of arrest and trial, with anarchical offences in the province; and among the earliest suspects against whom it was enforced were two members of the Bengal Legislative Council, and the chief executive officer of the Calcutta Municipal Corporation.

Not least among the anxieties of the time was the effect of political change on the public services which constitute the main structure of Indian administration. It was not only that members of the Indian Civil and other services found their position substantially altering, as they became transformed from the originators of policy into the subordinate executants of a quasi-parliamentary system. This was inevitable, but it was accompanied by virulent attacks from Indian politicians, who impugned the good faith of the services and made no secret of their desire to replace Englishmen by their own countrymen; and it was accentuated by the domestic anxiety which resulted from the growing cost of living, of passages to England and the like. Many valuable public servants retired prematurely, and the English universities soon stopped the supply of recruits of the type that had previously been available. In 1923 a royal commission was appointed to inquire into the whole problem. It recommended a large increase in the recruitment of Indians for the services, and the entrusting entirely to local Governments of recruitment for the "transferred" services. On the other hand, it advised several alleviations of the financial position of Europeans in the services, the adequate protection of the services in the execution of their duties, and the establishment of a Public Service Commission on the lines familiar in several of the Dominions.

Indians Abroad.—The Indian Relief Act of 1914 in the Union of South Africa and the outbreak of the war in the same year pushed into the background for a time the indignation felt in India about the treatment of its nationals in certain of the Dominions and Crown Colonies. But the grievance soon acquired increased impetus with the argument that Indian troops were considered good enough to fight by the side of forces from parts of the Empire which refused civic rights to Indians in peace time. Raised in a definite form at the Imperial Conferences of 1917 and 1918, the issue led to a "reciprocity agreement." Trouble revived, however, in various forms in Natal and the Transvaal, in East Africa and in Fiji; and the Imperial Conference of 1921 was again called into consultation. It passed a resolution to the effect that British Indians domiciled in another part of the Empire should be given recognition of their right to citizenship. South Africa, however, where it is estimated that 160,000 Indians are settled, declined to be a party to this declaration, and has uniformly urged its own responsibility for regulating the status of its inhabitants in its own interests. Trouble subsequently reached a dangerously acute point in Kenya, where at one time there seemed an imminent prospect of open hostilities between the British and the Indian settlers, and the whole question was again brought before the Imperial Conference in the same year. Four of the Dominions and the Colonial Office itself accepted the principle of consultation with the government of India on the status of Indians in the Dominions and Colonies; South Africa stood alone in refusing to hold out any hopes of the extension of the political rights of the Indian residents.

The North-West Frontier.—On the conclusion of the war which the new amir forced on India in 1919, there came clear evidence of a revival of Russia's old thrust towards India. It was with a view to fomenting revolutionary trouble in India that Bolshevik tentacles were pushed into Persia and Afghanistan; and when in 1921 a Russo-Afghan treaty was concluded, one of its chief features was the establishment of Russian consulates so near the Indian border as Kandahar and Jalalabad. The amir was not averse from playing off one of his neighbours against the other; and after inviting a mission from India to come to Kabul and negotiate an Anglo-Afghan treaty, he kept it dangling throughout 1921 before coming to final terms in November of that year. The conditions included the full independence of Afghanistan, and the opening of legations at London and Kabul.

Relations with the frontier tribes improved after the campaigns of 1919 and 1920; but in 1923 a gang of outlaws in Afghan territory was guilty of slaying two British officers near Landi Kotal, of shooting the wife and abducting the daughter (afterwards gallantly rescued) of an officer in Kohat cantonment, and of murdering another officer and his wife at Parachinar. Apart from the necessary punitive measures, the government of India initiated a permanent policy of controlling the Mahsud country, one of the chief storm-centres on the border. Dropping the plan of military occupation, they adopted a scheme of penetration of roads suitable for motor transport, guarded by local irregulars, and commanded by two strong posts at Raxmak and Manzai. Of even higher importance was the extension by five years of labour in the most forbidding country of the Khyber railway from Jamrud to Landi Khana; the first train through the Khyber Pass being run on Nov. 2, 1925.

Lord Irwin, Viceroy.—At the end of March 1926 Lord Reading laid down the office which he had filled with courage and distinction during a period of special difficulty. On retirement he received the high honour of promotion to Marquess: and he was succeeded by Lord Irwin of Kirby Moordale, a grandson of the Sir Charles Wood who had in 1854 sent out from the Board of Control an educational programme for India on which the existing system has largely been based. In spite of an earnest appeal for national unity with which the new Viceroy began his work, the year 1926 was marked by a greatly embittered continuance of the clash between Hindus and Mohammedans. The culminating point was the assassination by a Muslim fanatic of Swami Shradhananda, a much respected leader of Hindu orthodox who had headed a movement for the re-conversion of low-caste Hindus who had been absorbed by Islam. Apart from grave communal disturbances, 1926 was in politics the quietest year since the war. A Royal Commission on Indian Agriculture began its labours, and an important enquiry into the currency question was completed. As the result of long negotiations, visits and return visits by delegations from both sides, a settlement was reached on the grievances of Indians domiciled in South Africa: on its announcement in Feb. 1928 it was hailed by Gandhi, no mean authority on the subject, as an honourable compromise.

Events of 1927.—In January 1927 the new legislative palace at Delhi was formally opened and at once occupied. The third general election which was held in the preceding November had resulted in the grouping of the non-official members into three sections, the *Swaraj* or home-rule party, the nationalist party, and the Mohammedan *bloc*. The two former worked together in practice and in steady indiscriminating opposition to the government: the Mohammedans tended more and more to side with the government out of hostility to the Hindu combination: and the fortunes of government measures have been at the mercy of this fortuitous balance. The moderate or liberal element of earlier years has virtually disappeared: there is only a communal, and no real party, cleavage: and personal ambitions have played the chief part in dictating programmes. In the provinces the home-rule party did not secure its former ascendancy except in Madras: and the dyarchic system was re-established where it had been temporarily in abeyance. A noteworthy event was the election of a Madras lady by the legislative council of Madras as their vice-president; her membership of the council, however, was due, not

to popular suffrage, but to nomination by the provincial government. In general administration 1927 had a comparatively uneventful record of slow progress battling against *swaraj* obstruction. The rupee, in accordance with the advice of Sir E. Hilton Young's commission, was fixed at an exchange value of approximately 18 pence: a number of minor fiscal reforms were effected as incidents in a prosperity budget: and substantial measures were taken to relieve the provinces of a cherished grievance in the form of their contributions to the central exchequer.

All other topics of interest were overwhelmed by the announcement in Nov. 1927 of the commission to enquire into the working of the constitution of 1919.

Revision of the Constitution.—It is a statutory body whose duty is to advise on what further progress, if any, towards self-government should be arranged on the results of the first ten years' working of the 1919 experiment. It was appointed by the British parliament, and consisted exclusively of members of parliament, under the chairmanship of Sir John Simon. Its eight members included no Indian, and no person with experience of Indian administration; the open mind being thus ensured. Wide and loud was the outcry with which the announcement was received. The exclusion of Indians from the commission was denounced as an insult to India: the whole claim of Great Britain to adjudicate on India's fitness for independence was sheer racial arrogance: and the commission was to be boycotted and rendered impotent. Since then all other public business has been caught up in the ebb and flow of the boycott movement. It secured the defeat, with other important government measures, of a bill for the creation of a Reserve Bank, which was to be the coping-stone of the new currency edifice.

The Simon Commission.—On Feb. 3, 1928, the Simon Commission landed at Bombay. Strenuous efforts were made to meet them with a display of national resentment, a *hartal* or closing down of business, and so forth: but the response of the people at large was inadequate. The Commission did not risk an organized boycott by holding a public enquiry at this stage, and contented themselves by touring India and collecting opinions privately. At the same time Sir John Simon made generous proposals for the regular association of Indian leaders with his work; and when the Commission returned to England in spring, the expediency of a boycott was arousing serious doubts in the nationalist camp. Further endeavours were also made to remove the causes of difference between Hindu and Muslim: and an "All Parties" conference was held at Delhi in February and March. As a result, the nationalists took up the challenge that they had never made any constructive contribution to the settlement of India's political future. A constitution and a declaration of rights were drafted: the constitution moved on the familiar lines of dominion status, provincial autonomy, and a federal system for the States; there was to be manhood and womanhood suffrage; and all elections were to be by joint mixed electoral rolls, with no reservation of seats for minorities. On this last point the scheme shipwrecked. Its publication in August was followed by an immediate repudiation on the part of Mohammedans of practically every shade of political opinion. They declared communal electorates and the reservation of seats to be indispensable conditions of their joining in any demand for political advance. Excitement grew and was reflected, as usual, in a revival of sectarian riots and affrays. Meanwhile, the boycott crumbled, and all the provincial legislatures, with one exception, decided to co-operate with the Commission. While the Central Assembly hesitated on the same point, the Viceroy nominated a committee of its members to be associated in the enquiry. Accordingly, when Sir John Simon and his colleagues returned to India in the autumn to begin their public sittings, they found committees of both the central and the provincial legislatures ready to sit with them, for the examination of witnesses and consultation on their conclusions. (ME.)

INDIA, FRENCH, a general name for the French possessions in India—on the Coromandel coast, Pondicherry, Karikal and Yanaon; on the Malabar coast, Mahé and Calicut; and in Bengal, Chandernagore. There are a few "lodges" elsewhere, but they are merely nominal remnants of French factories. The total

area amounts to 203 sq.m., of which 113 sq.m. belong to the territory of Pondicherry. Pop. 42,725 (1926). The total population of the French possessions in India amounted in 1926 to 273,081 (estimate). Of these 92% were Hindus. These territories are found on the alluvial plains or in the neighbourhood of more or less important estuaries. The tropical vegetation is rich in valuable woods. Rice, cotton and earthnuts are cultivated and a few industries (oil works and weaving) arise out of the agricultural resources. The governor resides at Pondicherry, and is assisted by a private council. There are two tribunals of first instance (at Pondicherry and Karikal), one court of appeal (at Pondicherry) and five justices of the peace.

The first French expedition which was made to India is believed to have taken place in the time of Francis I. In his reign two ships were fitted out by some merchants of Rouen for trading in eastern seas, but they were never afterwards heard of. *La Compagnie des Indes* was formed under the auspices of Richelieu (1642) and reconstructed under Colbert (1664), sending an expedition to Madagascar. In 1667 the French India Company sent out another expedition, which reached Surat in 1668, where the first French factory in India was established. In 1741 Dupleix became governor of Pondicherry, and in 1744 war broke out between France and England. For the remaining history of the French in India see INDIA.

Danvers, *Records of the India Office* (1887); Henrique, *Les Colonies françaises* (1889); Lee, *French Colonies*, Foreign Office report (1900); *L'Année coloniale* (1900); Grolons, *La Compagnie française des Indes orientales de 1664 considérée comme Société de Commerce* (1911).

INDIAMAN, a name applied early in the eighteenth century to the large sailing ships belonging to the East India Company (q.v.) which was chartered by Queen Elizabeth on Dec. 31, 1600, the last day of the sixteenth century. This charter conferred the sole right of trading with the East Indies, that is, with all countries lying beyond the Cape of Good Hope or the Straits of Magellan. The length of the voyages involved and the bulk and value of the cargoes called for excellent ships. To meet this need the East India Company in 1609 constructed a dockyard at Deptford on the Thames, thus bringing about, as Monson writes, "the increase of great ships in England." By Earl Grey's act of 1833, the activities of the East India Company were greatly curtailed; in 1858 the Company ceased to exist, and the history of the "Indiamen" came to a natural end.

See *Anson's Voyages*, III., vii., 365.

INDIAN, an adjective originally derived from India, and properly applied to the peoples and products of that country, but later, through a geographical and historical blunder, transferred to the peoples of the New World, especially of North America and the West Indian Islands but also in a lesser degree to the inhabitants of Central and South America. The beginning of this confusion between widely different races, separated by half the world, marks a turning point in history. The Turkish conquests of the middle of the fifteenth century had blocked the earlier route to India across the Isthmus of Suez, depriving Europe of the rich and lucrative Eastern trade. Christopher Columbus, among others, came to the conclusion that India might be reached by another route, by sailing westward instead of eastward. He knew that the world was round, but he underestimated its size, and at the same time overestimated the eastward extension of Asia. Therefore, when he began his memorable voyage on August 3, 1492, his purpose was to sail to India; and when, two months and nine days later, he sighted land, he was convinced that he had reached India, or an island off the coast of India. As a natural consequence, he thought and spoke of the natives as Indians, and the misnomer has ever since attached itself to the races of the New World, excepting the Eskimo. Many attempts to repair the original error have been made, as in American Indian, abbreviated Amerindian, but the confusion still persists; thus Shakespeare's "Indian beauty" refers to Asia, his "dead Indian" to America. Indian corn refers to the New World, Indian ink to the Old. For North American Indians see NORTH AMERICA, *Ethnology*.

The word Indian, meaning an attribute of India, is derived from the Sanskrit, *sindhu*, a river, and, in particular, the great river

Indus. The European forms of the word are derived from the Persian *Hendu* and *Hind*.

INDIANA, popularly known as the "Hoosier State," is one of the north-central group of the United States of America, and the second State to be erected out of the old North-west Territory. It is located between lat. 37° 47' and 41° 50' N. and long. 84° 49' and 88° 2' W. Indiana is bounded on the north by Michigan and Lake Michigan, on the east by Ohio, on the south by Kentucky, from which it is separated by the Ohio river, and on the west by Illinois. In size Indiana ranks 37th among the States of the Union, its total area being 36,354 sq.m., of which 309 sq.m. exclusive of its Lake Michigan jurisdiction are water surface.

Physical Features.—Topographically, Indiana is similar to Ohio and Illinois, the greater part of its surface being undulating prairie land, with a range of sand-hills in the north and a chain of picturesque and rocky hills, known as "knobs," some of which rise to a height of 500 ft. above the surrounding country, in the southern counties along the Ohio river. This southern border of hills is the edge of the "Cumberland plateau" physiographic province. In the northern portion of the State there are a number of lakes of glacial origin of which the largest are English lake in Stark county, James lake and Crooked lake in Steuben county, Turkey lake and Tippecanoe lake in Kosciusko county and Lake Maxinkuckee in Marshall county. In the limestone region of the south there are numerous caves, the most notable being Wyandotte cave in Crawford county, next to Mammoth cave the largest in the United States. In the southern and south-central part of the State, particularly in Orange county, there are many mineral springs; the best known are French Lick and West Baden.

The larger streams flow in a general south-westerly direction, and the greater part of the State is drained into the Ohio through the Wabash river and its tributaries. The Wabash, which has a total length of more than 500 m., has its source in the western part of Ohio, and flows in north-west, south-west and south across the State, emptying into the Ohio river and forming for a considerable distance the boundary between Indiana and Illinois. Its principal tributaries are the Salamanie, Mississinewa, Wild Cat, Tippecanoe and White rivers. Of these the White river is by far the most important, being second only to the Wabash itself in extent of territory drained. It is formed by the confluence of its East and West Forks, almost 50 m. above its entrance into the Wabash, which it joins about 100 m. above the Ohio. Other portions of the State are drained by the Kankakee, a tributary of the Illinois; the St. Joseph and its principal branch, the Elkhart, which flow north through the south-west corner of Michigan and empty into Lake Michigan; the St. Mary's and another St. Joseph, whose

ROAD MILEAGE (OUTSIDE CITIES) ON DEC. 31, 1926, PER 100 SQ.M. OF LAND AREA, IN INDIANA, AS COMPARED WITH THE AVERAGE FOR CONTINENTAL U.S. THE BLACK SECTION REPRESENTS MILES OF SURFACE ROADS; WHITE SECTION, MILES OF EARTH ROADS

confluence forms the Maumee, which empties into Lake Erie; and the White Water, which drains a considerable portion of the south-west part of the State into the Ohio.

The soil of the greater part of the State consists of a drift deposit of loose calcareous loam, which extends to a considerable depth, and which is exceedingly fertile. In the Ohio and White Water river valleys a sandstone and limestone formation predominates. The north and north-central portions of the State, formerly rather swampy, have become since the clearing of the forest and drainage as productive as the south-central. The most fertile part of the State is the Wabash valley; the least fertile, the sandy region of small extent immediately south of Lake Michigan.

A large portion of the central and northern part and a considerable area in the south-west corner of Indiana have been included in drainage enterprises. About three-fourths of these enterprises were reported as having been organized for the purpose of draining land

that was swampy or so generally wet as to interfere with profitable cultivation. In 1920 54.3% of the total number of farms reported land having drainage. In the same year 8,308,844 ac. or 39.4% of the total farm-land was reported as provided with drainage and 1,717,068 ac. or 8.2% as needing drainage. The operating drainage enterprises in 1920 consisted of 17,470.7 m. of open ditch and 8,227.6 m. of tile drains, and represented a capital investment of \$31,047,682.

Climate.—The climate of Indiana is unusually equable. The mean annual temperature is about 52° F, ranging from 49° in the north to 54° in the south. The mean monthly temperature varies from 25° in the months of December and January to 79° in July and August. Cold winds from the Great Lakes region frequently cause a fall in temperature to an extreme of -25° in the north and north-central parts of the State. The mean annual rainfall for the entire State is about 43 in., varying from 35 in. in the north to 46 in. in the Ohio valley.

Government.—Indiana is governed under a Constitution adopted in 1851, which superseded the original State Constitution of 1816. An amendment to the Constitution may be proposed by either branch of the general assembly; if a majority of both houses vote in favour of an amendment and it is favourably voted upon by the general assembly chosen by the next general election, the amendment is submitted to popular vote and a majority vote is necessary for its ratification. The Constitution of 1816 had conferred the suffrage upon all "white male citizens of the United States of the age of 21 and upward," had prohibited slavery and had provided that no alteration of the Constitution should ever introduce it. The new Constitution contained similar suffrage restrictions, and further by Article xiii., which was voted upon separately, prohibited the entrance of negroes or mulattoes into the State and made the encouragement of their immigration or employment an indictable offence. This prohibition was held by the United States Supreme Court in 1866 to be in conflict with the Federal Constitution and therefore null and void. It was not until 1881 that the restriction of the suffrage to "white" males, which was in conflict with the 15th amendment (1870) to the Federal Constitution, was removed by constitutional amendment. Suffrage is now granted to all citizens 21 years old and upward who have lived in Indiana six months immediately preceding the election, and in the township for at least 60 days.

The Australian ballot was adopted in 1889. The general State election (up to 1881 held in October) takes place on the first Tuesday after the first Monday in November of even-numbered years. The governor and lieutenant governor (minimum age, 30 years) and the clerk of the supreme court are chosen in presidential years for a term of four years, the other State officers—secretary of State, attorney general, auditor, treasurer and superintendent of public instruction—every two years. The State legislature, known as the general assembly, which meets biennially in odd-numbered years and in special session summoned by the governor, consists of a senate of 50 members (minimum age, 25 years) elected for four years, and a house of representatives of 100 members (minimum age, 21 years) elected for two years. Two-thirds of each house constitute a quorum to do business. The governor has the veto power, but a bill may be passed over his veto by a majority of all elected members.

The judiciary consists of a supreme court of five members elected for districts by the State at large for a term of six years, an appellate court (first constituted in 1891) of six members elected for a term of four years and a system of circuit courts (75 in 1927) with judges elected for six years.

The system of local government has undergone radical changes in recent years. A law of 1899, aimed to separate the legislative and executive functions, provided for the election of legislative bodies in every township and county. These bodies have control of the local expenditures and tax levies, and without their consent the local administrative officers cannot contract debts. In 1905 a new municipal code, probably the most elaborate and complete local government act in the United States, providing for a uniform system of government in all cities and towns, went into effect. Its controlling principle was the more complete separation of the

executive, legislative and judicial powers. For this purpose all cities are divided into five classes according to population, the power being concentrated and simplified by degrees in the case of smaller cities, and reaching a maximum of separation and completeness in class I; i.e., cities of 100,000 and over, which included only Indianapolis. In 1921 the system was amended so as to allow cities, at their option, to provide for city planning and to adopt the city manager or commission form of city government. Communities under 2,500 in population are regarded as towns, and have a separate form of government by a board of trustees.

SOCIO-ECONOMIC LIFE

Population.—The population of Indiana, according to the Federal census of 1920, was 2,930,390, and the rank of the State

in the Union as regards population was 11th. The population as of July 1, 1928, was 3,176,000, as estimated by the U.S. census bureau. In 1810, the year following the erection of the western part of Indiana into Illinois Territory, the population was 24,520; in 1820 it had increased to 147,178; in 1850 to 988,416; in 1870 to 1,680,637; in 1890 to 2,192,404; in 1900 to 2,516,462; and in 1910 to 2,700,876. The density of population in 1920 was 81.3 to the sq.m.; in 1910, 74.9. The foreign-born white population in 1920 amounted to 150,868, or 5.3% of the whole, and the negro population to 80,810 or 2.8%. Of the foreign-born population Germans (37,377), Poles (17,791), Hungarians (9,351), Austrians (9,100) and English (8,522) were the most numerous. The urban population (in places over 2,500) was 50.6% of the whole in 1920, as against 42.4% in 1910. The six cities of Indiana with a population of 50,000 or more in 1920 were:

	1920	1910	Increase	Estimated 1928
			%	
Indianapolis . . .	314,194	233,650	34.5	382,100
Fort Wayne . . .	86,549	63,933	35.4	105,300
Evansville . . .	85,264	69,647	22.4	98,100
South Bend . . .	70,983	53,684	32.2	86,100

Finances.—The total true receipts for the year ending Sept. 30, 1926, were \$44,886,461. Of this amount the tax on property furnished \$14,793,997, or 33% of the total; poll taxes, \$540,198, or 1.2%; insurance taxes, \$1,578,867, or 3.5%; inheritance taxes, \$1,047,238, or 2.3%; gasoline taxes, \$8,641,337, or 19.3%; Federal aid, \$3,013,926, or 6.7%; fees, \$8,070,624, or 18%; the remainder came from miscellaneous sources. The total true disbursements for the above period were \$42,125,456. Of this amount, the chief disbursements were as follows: State department schools, \$6,597,304, or 15.7%; State highways, \$12,375,512, or 5.4%; schools, \$5,536,764, or 13.1%; universities and normal schools, \$6,597,304, or 15.7%; State highways, \$12,375,512, or 29.4%; gasoline fund, \$2,462,694, or 5.9%; and benevolent institutions, \$6,016,001, or 14.3%. The balance in the treasury on Sept. 30, 1926, was \$12,218,960. The total State debt on the above date was \$1,689,000, held as State bonds.

Education.—Indiana has a well-organized free public school system. Provision was made for such a system in the first State Constitution, by utilizing school lands set aside in all the Northwest Territory by the Ordinance of 1787, but the existing system is

of later growth. The first step toward such a system was a law of 1824 which provided for the election of school trustees in every township and for the erection of school buildings, but made no provision for support. Therefore, before 1850 what schools there were were not free. The Constitution of 1851 made further and more complete provisions for a uniform system, and on that basis the general school law of 1852 erected the framework of the existing system. It provided for the organization of free schools, supported by a property tax, and for county and township control. The movement, however, was retarded in 1858 by a decision of the supreme court holding that under the law of 1852 the system was not "uniform" as provided for by the Constitution. In 1865 a new and more satisfactory law was passed, which, with supplemental legislation, is still in force. Under the existing system administrative control is vested in a State superintendent elected biennially. County superintendents, county boards, city boards and township trustees are also chosen, the last possessing the important power of issuing school bonds.

In 1921 the State increased the tax for common school support as well as for the support of the higher educational institutions, and provision for teachers' pensions was enacted. There was a tax levy of five cents on each \$100 of taxable property for the support of the higher educational institutions of the State, producing about \$2,750,000, and a levy of a fraction of a cent for vocational education, which had been introduced by a law of 1913, producing yearly about \$115,000. In 1925 the tax levy for higher education was repealed and the State schools received special appropriations. The expenditures for public elementary and secondary schools in 1925 were \$60,288,000 as compared with \$35,764,000 in 1920; the *per capita* expenditure based on population 5-17, inclusive, was \$82.14 and \$50.18, respectively. The proportion of illiterates is very small; in 1920 only 2.2% of the population (of 10 years old or over) were unable to read and write. Of the total public school enrolment (642,496) in 1925, 518,637 were in the kindergarten and elementary grades and 123,859 in secondary schools.

The average number of days attended per year per pupil enrolled increased from 125.8 in 1920 to 164.5 in 1925. School attendance has been compulsory since 1897.

The State-supported institutions for the training of teachers are the State normal school (organized 1870) at Terre Haute and the Ball Teachers' college (organized 1918) at Muncie. Other normal schools, which are on the State's "accredited" list but not supported by it, are the Central normal college at Danville and the Teachers' College of Indianapolis at Indianapolis. A State college was opened in 1824 at Bloomington; it was rechartered in 1838 as Indiana university. Purdue university (organized 1869) at Lafayette is the State's school of agriculture and mechanical arts. It received the benefit of the Federal land grants under the Morrill and subsequent acts. In 1927 there were 19 non-State supported educational institutions of college rank within the State. The better known of these included the University of Notre Dame (1842, Roman Catholic) at Notre Dame; DePauw university (1837, Methodist Episcopal) at Greencastle; Butler college (1855, Christian) at Indianapolis; Wabash college (1832, non-sectarian) at Crawfordsville; and Valparaiso university.

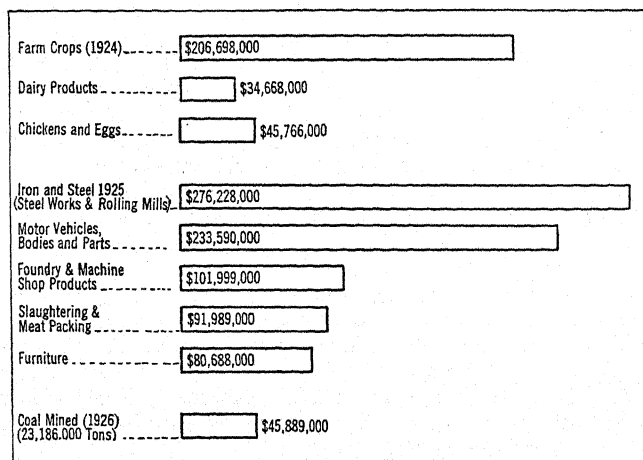

Charities and Correction.—The charitable and correctional institutions of Indiana are well administered and form one of the most complete and adequate systems possessed by any State in the Union. The State was one of the first to establish schools for the deaf and the blind. The State School for the Deaf was established in 1844, and the School for the Blind in 1847, both being in Indianapolis. The first State hospital for the insane was opened in Indianapolis in 1848 and became the Central State hospital in 1883; other similar institutions are the Logansport State hospital at Logansport, the Richmond State hospital at Richmond, the Evansville State hospital at Evansville, and the Madison State hospital at North Madison. Institutions for the feeble-minded include the School for Feeble-minded Youths at Ft. Wayne, the Farm Colony for Feeble-minded at Butlerville, and the Village for Epileptics at Newcastle. There is a State Soldiers home at LaFayette, a Soldiers and Sailors Orphans' home at Knightstown, a State sanatorium at Rockville and the Indiana

University hospitals at Indianapolis. There are six correctional and penal institutions: the Boys' school at Plainfield, the Girls' school at Indianapolis, the prison for women at Indianapolis, the State reformatory at Pendleton, the State prison at Michigan City and the State farm at Putnamville. Indiana has a habitual-criminal law, and a law providing for the sterilization of mental degenerates, confirmed criminals and rapists. There are also an adult probation law and a juvenile court law, the latter applying to every county in the State. Each of the State institutions mentioned above is under the control of a separate bipartisan board. The whole system of public charities is under the supervision of a bipartisan board of State charities (1889), which is appointed by the governor.

INDUSTRIAL ACTIVITY

Industry, Trade and Transportation.—Agriculture has always been an important industry of the State of Indiana. According to the 1925 census of agriculture, the farm population was 798,157, or 25.8% of the total population. In 1920 the farm acreage was 21,063,000, or 91.3% of the total land area; by 1925 the acreage had decreased to 19,915,000, or 86.3% of the total area. The actual acreage of crop land in 1925 was 11,981,000, and 10,616,000 ac. produced crops for harvest. The number of farms has also shown a steady decrease since 1900. In 1925 the total number of farms was 195,789 as compared with 205,126 in 1920 and 221,897 in 1900. The value of all farm property increased rapidly during the World War period, reaching a value of \$3,042,311,000 in 1920; by 1925 the total value of all farm property had decreased to \$1,931,742,000. The proportion of farms rented comprised 29.2% of the whole number. The average size of farms, which in 1850 was 136.2 ac., was 101.7 ac. in 1925.

Indiana was 16th in the value of its farm crops in 1926, the total product being valued at \$225,000,000. The principal crops in which the State has maintained a high relative rank are Indian corn, oats, rye and hay; the acreage devoted to oats and rye has increased considerably since 1910. In 1926, according to the Department of Agriculture, the acreage of Indiana corn was 4,672,000 (6th of the States), and the yield was 170,085,000 bu. (4th of the States); of wheat, 1,703,000 ac. (12th of the States)

VALUE OF ANNUAL OUTPUT OF CERTAIN IMPORTANT PRODUCTS. THE AGRICULTURAL ITEMS ARE FOR 1924, THE MANUFACTURES FOR 1925 AND COAL FOR 1926

were planted, and the crop was 34,048,000 bu. (9th of the States); from the 2,234,000 ac. (6th of the States) devoted to oats the yield was 67,020,000 bu. (7th of the States); the 2,015,000 ac. of hay produced 2,536,000 tons.

Other important staple crops were potatoes, rye and barley, of which the crops in 1926 were respectively 3,840,000 bu., 2,102,000 bu. and 925,000 bu. The tobacco crop in 1926 was 14,913,000 lb. valued at \$1,491,000. In the production of onions (2,539,000 bu.) the State ranked second only to New York; in the acreage devoted to the commercial tomato crop, Indiana ranked first. Orchards in 1926 produced 4,100,000 bu. of apples, 900,000 bu. of peaches and 328,000 bu. of pears. The canning industry both

for fruits and vegetables is valuable (\$31,674,387 in 1925).

The number of live-stock reported on Jan. 1, 1927, was 533,000 horses, valued at \$42,816,000; 98,000 mules, valued at \$8,381,000; 699,000 sheep, valued at \$7,138,000; 2,764,000 swine (6th in rank among the States), valued at \$46,988,000; and 1,308,000 cattle, valued at \$66,456,000.

Indiana ranked 12th in value of mineral products for 1925. The production in the above year showed an increase of 111.8% over the corresponding figures for 1919. The chief products, in order of value in 1925, were: coal, cement, stone and clay. The 22,839,000 tons of coal produced in 1926 represented, in value, about 50% of the total mineral products of the State. Indiana continued to rank 6th among the States of the Union as a producer of coal. The coal-producing area of the State is part of the eastern-interior coal-field which extends into Illinois and Kentucky and covers approximately 7,500 sq.m. in 22 counties in the south-western part of Indiana. The deposit consists of workable veins, 50 to 220 ft. in depth, and averaging 80 ft. below the surface. It is a high-grade block, or "splint" coal, remarkably free from sulphur and rich in carbon, peculiarly adapted to blast-furnace use. The limestone industry was second in importance. The chief enterprises were in the Bedford-Bloomington district in Lawrence and Monroe counties. This district produced about 70% of the limestone used in the United States for building, the 1924 output being 3,824,440 tons, valued at \$17,269,407. Indiana oolitic limestone is used in nearly every State and also abroad. Beds of brick-clays and potters' clay are widely distributed throughout the State, the total value of clay products in the year 1925 being \$18,037,932. Marls adapted to the manufacture of Portland cement are found along the Ohio river, and in the lake region of the north. Sand and gravel in 1925 had a value of \$5,275,743.

The petroleum and natural gas industries were once of great importance in Indiana. In 1906 the State ranked 5th in the Union in the value of natural gas produced and 6th in petroleum; in 1926 the State's rank was 14th and 17th respectively. The natural gas production in 1925 (1,168,000,000 cu.ft.) showed a slight increase over that of preceding years, while the petroleum production for the foregoing year (829,000 bbl.) showed a decrease. The industry is located in two fields, the Lima-Indiana field in east-central Indiana, which extends into Ohio, and the south-western Indiana field, which is continuous with the Illinois field. There are many mineral springs in the State, and there are famous resorts at French Lick and West Baden in Orange county. A large part of the water bottled is medicinal. In 1923 500,064 gal. of mineral water, valued at \$152,082, were sold. The total mineral production of the State in 1925 had a value of \$111,833,732.

In the value, extent and producing power of her manufacturing industries Indiana has advanced rapidly. This was largely due to excellent transport facilities, to the discovery and development of natural gas and an abundant coal supply. The number of manufacturing establishments in the State was 8,022 in 1914, 4,772 in 1925; the number of wage-earners was 197,503 in 1914 and 280,854 in 1925, an increase of 42.2%; and the value of their total product was \$730,795,000 in 1914 and \$2,125,023,000 in 1925, an increase of 190.8%. As compared with other States of the Union in value of manufactured products, Indiana ranked 9th in 1925. The most important manufactured products in 1925 were iron and steel, valued at \$334,236,625 (\$67,008,451 for

blast-furnace products and \$267,228,174 for steel and roller-mill products). Next in importance was the manufacture of motor vehicles (\$179,510,952) and motor vehicle parts (\$54,078,861). Other manufactured products exceeding \$30,000,000 in value in 1925 were: those of machine shops and foundries, \$101,999,155; slaughtering and meat-packing, \$91,988,643; furniture, \$80,687,630; electrical machinery and apparatus, \$77,555,648; electric and steam railway cars, \$59,024,272; construction in steam railway repair shops, \$57,073,134; coke, not including gas-house production, \$44,721,218; flour and grain mill products, \$41,484,262; glass, \$36,199,554; canned fruits and vegetables, \$31,674,387; butter, cheese and condensed milk, \$30,231,115; and bread and bakery products, \$30,223,581. The most important manufacturing centres were Indianapolis, South Bend, East Chicago, Gary, Ft. Wayne, Evansville, Hammond, Anderson, Muncie, Michigan City, Mishawaka, Elkhart, Kokomo, Marion, La Porte and Terre Haute, each having a gross annual product of more than \$20,000,000. Indianapolis, with a product valued at \$344,924,907, was by far the chief industrial centre. It was the centre of the slaughtering and meat-packing industry and the printing and publishing of newspapers and periodicals; it was also an important centre for the motor vehicle, furniture and foundry industries. The cities of East Chicago, Gary and Hammond were the centre of the State's iron and steel industry. South Bend was the principal manufacturing centre of Indiana's motor vehicle and clock and watch industries.

During the early period, the settlement of the northern and central portions of the State was greatly retarded by the lack of highways or navigable waterways. The Wabash and Erie canal (1843), which connected Lake Erie with the Ohio river, entering the State in Allen county, east of Ft. Wayne, and following the Wabash river to Terre Haute and the western fork of the White river from Worthington, Greene county, to Petersburg, Pike county, whence it ran south-south-west to Evansville; and the White Water canal from Hagerstown, Wayne county, mostly along the course of the White Water river, to Lawrenceburg, on the Ohio river, in the south-eastern corner of the State, although now abandoned, served an important purpose in their day. The completion (about 1850) of the national road, which traversed the State, still further aided the internal development. With the beginning of railway construction (about 1847), however, a new era was opened. Indiana is unusually well served with railways, which form a veritable network of track in every part of the State. It is traversed by nearly all the great transcontinental trunk-line systems, and also by important north and south lines. The total railway mileage in Jan., 1925, was 7,187 miles. This figure represents a slight decrease from the 7,479 m. in operation in 1915. There was great development also in interurban electric lines, which have been adapted both to passenger and to light freight and express traffic; in 1925 there were 28 street and interurban electric lines within the State with a mileage of 2,485. The State highway system under the control of the highway commission was, on Jan. 1, 1927, 4,263 m., of which 4,155 m. were surfaced. During 1926 376.7 m. of new surfacing were laid. The annual expenditures for rural highways under the supervision of the State highway department increased rapidly from the \$401,000 spent in 1919 to \$14,920,000 in 1924 and \$14,518,000 in 1925.

History.—Of the prehistoric inhabitants of Indiana little is known, but extensive remains in the form of mounds and fortifications abound in every part of the State. Upon the earliest arrival of Europeans the State was inhabited chiefly by the various tribes of the Miami confederacy, a league of Algonquin Indians formed to oppose the advance of the Iroquois. The first Europeans to visit the State were probably French *coureurs de bois* or Jesuit missionaries. Apparently a French trading-post was in existence on the St. Joseph river of Michigan about 1672, but it was in no sense a permanent settlement. It also seems probable that the Wabash-Maumee portage was known to Father Claude Jean Allouez as early as 1680. A few years later this portage came to be generally used by traders, and the necessity of establishing a base on the upper Wabash as a defence against the Carolina and Pennsylvania traders became evident; however, the first perma-

nent settlement was not made until well into the 18th century. The military post at Vincennes was founded about 1731 by François Margane, Sieur de Vincennes (or Vincent), but it was not until about 1735 that eight French families were settled there. Vincennes, which thus became the first actual white settlement in Indiana, remained the only one until after the Revolutionary War, although military posts were maintained at Ouiatenon and at the head of the Maumee, the site of the present Ft. Wayne, where there was a French trading-post (1680) and later Ft. Miami. After the fall of Quebec the British took possession of the other forts, but not at once of Vincennes, which remained for several years under the jurisdiction of New Orleans, both under French and Spanish rule. The British garrisons at Ouiatenon and Ft. Miami (near the site of the later Ft. Wayne) on the Maumee were captured by the Indians as a result of the Pontiac conspiracy. All Indiana was united with Canada by the Quebec act (1774), but it was not until three years later that the forts and Vincennes were occupied by the British, who then realized the necessity of ensuring possession of the Mississippi valley to prevent its falling into the hands of the rebellious Colonies. Nevertheless, in 1778 Vincennes fell an easy prey to agents sent to occupy it by George Rogers Clark (*q.v.*), and although again occupied a few months later by the British under Gen. Henry Hamilton, the lieutenant governor at Detroit, it passed finally into American control in Feb., 1779, as a result of Clark's remarkable march from Kaskaskia. Ft. Miami remained in British hands until the close of the war.

The first American settlement was made at Clarksville, between the present cities of Jeffersonville and New Albany, at the Falls of the Ohio (opposite Louisville), in 1784. The decade following the close of the Revolutionary War was one of ceaseless Indian warfare. The disastrous defeats of Gen. Josiah Harmar (1753-1813) in Oct., 1790, on the Miami river in Ohio, and of Gov. Arthur St. Clair on Nov. 4, 1791, near Ft. Recovery, O., were followed in 1792 by the appointment of Gen. Anthony Wayne to the command of the frontier. By him the Indians were signally defeated in the battle of Fallen Timbers (or Maumee Rapids) on Aug. 20, 1794, and Ft. Wayne, Ind., was erected on the Maumee river. On Aug. 3, 1795, at Greenville, O., a treaty was concluded between Wayne and 12 Indian tribes, and a narrow slice of the east-south-eastern part of the present State (the disputed lands in the valley of the Maumee) and various other small but not unimportant tracts were ceded to the United States. Then came several years' respite from Indian war, and settlers began at once to pour into the region. The claims of Virginia (1784) and the other eastern States having been extinguished, a clear field existed for the establishment of Federal jurisdiction in the "Territory North-west of the Ohio," but it was not until 1787 that by the celebrated ordinance of that year such jurisdiction became an actuality. In 1800 the North-west Territory was divided, and from its western part (including the present States of Indiana, Illinois and Wisconsin, the north-east part of Minnesota, and a large part—from 1803 to 1805 all—of the present State of Michigan) Indiana Territory was erected, with Gen. William Henry Harrison as first governor, and Vincennes as the seat of government. Harrison made many treaties with the Indians, the most important being that signed at Ft. Wayne on June 7, 1803, defining the Vincennes tract transferred to the United States by the Treaty of Greenville; those signed at Vincennes on Aug. 18 and 27, 1804, transferring to the United States a strip north of the Ohio river and south of the Vincennes tract; that concluded at Grouseland on Aug. 21, 1805, procuring from the Delawares and others a tract along the Ohio river between the parcels of 1795 and 1804; and the treaties of Ft. Wayne, signed on Sept. 30, 1809, and securing one tract immediately west of that of 1795 and another north of the Vincennes tract defined in 1803. In Jan., 1805, Michigan Territory was erected from the northern part of Indiana Territory, and in the following July the first general assembly of Indiana Territory met at Vincennes. In March, 1809, the territory was again divided, Illinois Territory being established from its western portion; Indiana was then reduced to its present limits. In 1810 began the last great Indian war in Indiana, in

which the confederated Indians were led by Tecumseh, the celebrated Shawnee chief; it terminated with their defeat at Tippecanoe (the present battle ground) by Gov. Harrison on Nov. 7, 1811. After the close of the second war with Great Britain, immigration began again to flow rapidly into the territory, and, having attained a sufficient population, Indiana was admitted to the Union as a State by joint resolution of Congress Dec. 11, 1816. The seat of government was established at Corydon, whither it had been removed from Vincennes in 1813. In 1820 the site of the present Indianapolis was selected for a new capital, but the seat of government was not removed thither until 1825.

The first great political problem presenting itself was that of slavery, and for a decade or more the only party divisions were on pro-slavery and anti-slavery lines. Although the Ordinance of 1787 actually prohibited slavery, it did not abolish that already in existence. Slavery had been introduced by the French, and was readily accepted and perpetuated by the early American settlers, almost all of whom were natives of Virginia, Kentucky, Georgia or the Carolinas. According to the census of 1800 there were 175 slaves in the Territory. It was but natural, therefore, that efforts should at once have been made to establish the institution of slavery on Indiana soil, and as early as 1802 a convention, called to consider the expediency of slavery, asked Congress to suspend the prohibitory clause of the ordinance for ten years, but a committee of which John Randolph of Virginia was chairman reported against such action. Within the Territory attempts to escape the effects of the ordinance led to the enactment of a law regulating the status of "servants" and another which established a system of indenture. By 1808 the opponents of slavery, found chiefly among the Quaker settlers in the south-eastern counties, began to awake to the danger that confronted them, and in 1809 elected their candidate, Jonathan Jennings (1776-1834), to Congress on an anti-slavery platform. In 1810, by which year the number of slaves had increased to 237, the anti-slavery party was strong enough to secure the repeal of the indenture law, and the State Constitution of 1816 pronounced strongly against slavery. The liberation of most of the slaves in the eastern counties followed; and some slave-holders removed to Kentucky. In 1830 there were only three slaves in the State, and the danger of the establishment of slavery as an institution on a large scale was long past.

The problem of "internal improvements" came to be of paramount importance in the decade 1820-30. In 1827 Congress granted land to aid in the construction of a canal to connect Lake Erie and the Ohio river. This canal was completed from the St. Joseph river to the Wabash in 1835, opened in 1843 and later abandoned. In 1836 the State legislature passed a law providing for an elaborate system of public improvements, consisting largely of canals and railways. The State issued bonds to the value of \$10,000,000, a period of wild speculation followed, and the financial panic of 1837 forced the abandonment of the proposed plan and the sale to private persons of that part already completed. The legislature authorized the issue of \$1,500,000 in Treasury bonds, which by 1842 had fallen in value to 40 or 50% of their face value. A new Constitution was adopted in Feb., 1851, by a vote of 109,319 against 26,755.

Despite its large Southern population, Indiana's answer to President Lincoln's first call for volunteers at the outbreak of the Civil War was prompt and spirited. In all the State furnished 208,000 officers and men for the Union armies, besides a home legion of some 50,000, organized to protect the State against possible invasion. The efficiency of the State military organization as well as that of the civil administration during the trying years of the war was largely due to the extraordinary ability and energy of Gov. Oliver P. Morton, one of the greatest of the "war governors" of the North. The problems met and solved by Gov. Morton, however, were not only ones of furnishing troops as required. The legislature of 1863 and the State officers were opposed to him politically, and did everything in their power to thwart him and deprive him of his control of the militia. The Republican members seceded, legislative appropriations were blocked, and Gov. Morton was compelled to take the extra-constitutional step of arranging with a New York banking-house for the payment of

the interest on the State debt, of borrowing money for State expenditure on his own responsibility, and of disbursing money in disregard of the State officers.

Furthermore Indiana was the principal centre of activity of the disloyal association known as the Knights of the Golden Circle or Sons of Liberty, which found a ready growth among the large Southern population. The Knights of the Golden Circle at first confined their activities to the encouragement of desertion and resistance to the draft, but in 1864 a plot to overthrow the State Government was discovered, and Gov. Morton's prompt action resulted in the seizure of a large quantity of arms and ammunition, and the arrest, trial and conviction of several of the leaders. In June, 1863, the State was invaded by Confederate cavalry under Gen. John H. Morgan, but most of his men were captured in Indiana and he was taken in Ohio.

Politically Indiana has been rather evenly divided between the parties. Before the Civil War, except when William Henry Harrison was a candidate for the presidency, its electoral vote was generally given to the Democratic Party, to which also most of its governors belonged. After the war the control of the State alternated between the Republican and Democratic Parties. In legislation the State has been more progressive. Laws were passed establishing the direct primary for State nominations (1915), labour protection (1915), a State prohibition act (1917), a highway commission (1917), a system of State parks (1919) and a State budget system (1921).

INDIANA, a borough in the west central part of Pennsylvania, U.S.A., 46m. N.E. of Pittsburgh; the county seat of Indiana county. It is on Federal highways 119 and 422, and is served by the Buffalo, Rochester and Pittsburgh and the Pennsylvania railways. The population in 1920 was 7,043 (95% native white) and was estimated locally at 10,000 in 1928. Indiana is beautifully situated in the foot-hills of the Alleghenies, and is in the midst of an important coal-field. It has an extensive trade, is the chief shipping point and shopping centre for the county, and there are glass works and other manufacturing industries. The Indiana State Teachers' college (opened 1875) has an enrolment of over 1,300.

INDIAN AND SINHALESE ART AND ARCHAEOLOGY. Indian religion and ritual exist in two forms, known to Indians as the Vedic and the Āgamic traditions, but more often designated by western scholars as respectively Āryan and Brahmanical, and Dravidian (Southern) and popular. Vedic (Āryan) religion consisted in a worship of the great powers of nature by means of hymns and sacrifices (*yajña*), without any use of temples or images, or any devotional cult properly so to be described. On the other hand, the much older and quantitatively predominant element of the population worshipped local and tutelary deities, powers of nature conceived as personal beings; these deities included the Yakṣas (genii, tree-spirits, sources of life and abundance), Nāgas (dragons, spirits of springs and lakes), and innumerable goddesses of fecundity or disease, the Śaktis of later Hinduism. To this Āgamic tradition belonged an elaborate cosmology, many myths, the doctrines of reincarnation and acts (*saṃsāra* and *karma*), the practice of asceticism (*saṃnyāsa*) and ecstatic meditation (*yoga*), which appear only

late in Vedic literature.

Significance and Character.—The indigenous divinities were worshipped with devotion (*bhakti*) as personal beings, with a ritual (*pūjā*, a non-Āryan word referring to the anointment of sacred objects) which included offerings of flowers, food, lights and incense; and for this ritual images and temples, though of impermanent materials, wood and clay, must have been in use from a very early period.

The Vedic culture is gradually penetrated by indigenous belief and closes with the reactionary teachings of the Upaniṣads and Buddhism, where *yajña* is discounted, *pūjā* not considered, the goal is Release, the means is Knowledge. Meanwhile there was developing a higher and inclusive devotional theism, in which the indigenous deities are fused with those of the Vedas, and interpreted in the light of philosophic and psychological speculation. The great system (see HINDUISM) thus built up, sanctioned on the one hand by scripture and on the other by popular belief, became a truly national vehicle of thought; Hindu theology and myth, in verbal and visual expression, provided means of statement for all that was felt and thought about the soul of man and the nature of the universe. At the same time, new divinities came into being, amongst others the Buddha himself; for the prevailing tendency involved in iconolatry, cult and ritual even such systems as those of Buddhism and Jainism which had originated as purely psychological and ascetic disciplines.

For some centuries before and after the beginning of the Christian era the dominant mode of creative thought was theological; and we must realize that all the arts were governed by a great enthusiasm like that of the cathedral builders of mediaeval Europe, and in all enduring aspects and in their greatest splendour, in the service of the churches, upon whose endowment and adornment was lavished enormous wealth.

Long after the first creative impulses had been crystallised in the mediaeval period, there can still be traced successive developments of thought and feeling, modifications and elaborations of the older iconography, with the result that India, despite the destruction wrought by Mohammedan invaders, is even to-day covered with magnificent temples and a wealth of sculpture in which the spiritual and material history of two millenniums are visibly recorded. Further, the same initial impulses, translated to other lands and moulded by the imagination of other races, Pyu, Thai, Khmer, Malay and Polynesian, created other and scarcely less significant and varied cycles of art in Further India and Indonesia, and influenced profoundly the spiritual and artistic development of Central Asia, China, Korea and Japan.

Thus Indian art is essentially a hieratic art devoted to the exposition of the personality and acts of deities, and providing for their service. Authoritative texts declare that the making of images of deities leads to heaven, not the making of likenesses of men; that only that which accords with the canons is beautiful in the eyes of the discerning, not that which pleases individual fancy.

Hieratic Art.—But while Indian works evoke aesthetic experiences when beheld by alien eyes, Indian and European art are not identical in kind; the intention is different. Nor is there identity of method. In its main development, sculpture and architecture, Indian art was not produced with a view to aesthetic experience, nor even regarded as "art." Images, in particular, were not regarded as works of art but as means (*sādhana*) of edification.

An image is a piece of apparatus (*yantra*) employed in personal devotions, the object of which is an identification in consciousness of worshipper and deity. In the words of a well-known text, the deity can only be worshipped (in spirit and in truth) in so far as the worshipper becomes the deity. For this spiritual exercise *yantras* of two kinds are employed, one purely geometrical and linear, the other three-dimensional and more or less anthropomorphic or theriomorphic. Both types are alike in kind; both are equally externalisations of mental visions evoked in *dhyāna* with a view to *saṃādhi*.

The obtaining of this mental visualisation (which is more essential than its material realisation) is a process of *yoga*.

Such a visualisation differs from those present in normal vision: it is more vivid; it fills the whole field of view; all parts are equally and simultaneously present; the relation of these parts is not organic, nor on the other hand accidental, but ideally determined; such an image can only represent a condition of being, or to use a more strictly Indian term, a type of activity.

Such an image is not a memory image, which is the foundation

FIG. 1.—YANTRA, A DIAGRAM FOR WORSHIP

of all realistic art, inasmuch as time passes between the moment of vision and that of execution.

What may at first sight look like the observation of nature at Amarāvati or Ajantā, is simply the most vital and the most felt part of Indian art, where the worshipper attains the most complete *samādhi*, the artist is most completely and literally identified with his subject. Critically examined, this art reveals no knowledge of anatomy, but rather a deep understanding of life, of emotion, and of the language of gesture, long codified in the *Nāṭya Sāstra*. (See DANCE IN INDIA.) Nor are its themes confined to those set forth in terms of human life; side by side with these are dogmatic and mythological forms unparalleled in nature.

Narrative and Decorative Art.—A part of Indian art is secular. There exist, beside the cult image, both narrative arts, and an Industrial Art, or Arts and Crafts. The narrative art such as is used to illustrate *Jatākas* or the Epics or the Kṛṣṇa legend is not hieratic to the same degree as the cult image, but a dramatic presentation comparable to the stage. It is nevertheless governed by principles similar to those which determine the nature of the cult image: the use of formulae is general, and the part of the spectator quite distinct from that of mere perception. A typical peculiarity of Indian (and in general Oriental) art is the kind of perspective known as vertical projection, whereby the landscape is presented as seen from a height, so that the horizon almost reaches the upper edge of the frame; the planes are differentiated in the sense that an object or figure behind another is represented as above it, while the atmosphere, apparently reduced to the narrow space remaining above the horizon, is really brought forward to embrace the whole representation together with the spectator.

Although in Sanskrit literature we hear much of portraits of individuals recognized as likenesses, these are invariably drawn from memory, in the absence of the model, so far at least as the actual references inform us.

Further, Indian art reveals nothing like *genre*. The nude, for example, while sometimes represented with a frankness disconcerting to European eyes, is never studied or treated for its own sake, as in European art, and only appears as symbolism or narra-

tive may require. In the same way landscape is never represented for its own sake.

Thus the narrative art of India is of the same kind as the purely hieratic art. All true pattern is of this kind; this is especially evident in its repetitive character and in a mathematical rather than organic relation of the parts. Accordingly, the industrial and "decorative" arts in India cannot be sharply divided from the "higher" arts. In both, design and formula, rather than imitative shapes, are found; definite meanings are present in both, for Oriental ornament is never originally without, and very rarely loses, a precise significance, and is never "merely" decorative.

A Theory of Beauty.—India developed as a means of literary criticism a theory of aesthetic experience of considerable importance in the history of aesthetic theory.

A work of art is a statement informed by flavour (*rasa*); there are nine such flavours, the Erotic, Heroic, Odious, Furious, Terrible, Humorous, Wondrous, Pathetic and Peaceful. The component elements of a work of art (physical stimulants of aesthetic experience) are Determinants (*vibhāva*, theme, etc.), Consequents (*anubhāva*, deliberate actions), Moods (*bhāva*, thirty-three transient, e.g., joy, impatience, and nine permanent, viz., the nine *rasas* listed above), and Involuntary Emotional Conditions (*sattvabhāva*).

Aesthetic experience (*rasāsvādāna*) is the tasting of *rasa*, and depends mainly on the innate and acquired sensibility of the spectator (*rasika*). To appreciate the art of India from the standpoint of life it must be studied not only from this point of view as form, but also as meaning and with reference to use.

The Artist.—A general term covering both sculpture, reliefs and painting is *citra*; this word can also be used in a more restricted sense with reference to painting only. *Silpa* is the practical activity of the craftsman, rather than "art" in a modern sense. The artist or craftsman is designated as *śilpīn*, *sthapati*, *karmāra*, *rūpa-kāra*, *citra-kāra*, etc. The higher craftsmen practise many arts; an architect, for example, will also be a sculptor, bronze founder and goldsmith. On the other hand workers in iron, weavers, potters and the like are restricted to a single craft. No artist is solely a designer, like a modern architect; the Indian architect is, during the greater part of his life, a manual worker.

In the Indian idea, the "artist," the *śilpīn*, is not a peculiar individual with a special gift for experience, but simply a trained man meeting a general demand. His vocation is hereditary, and he receives his education in the workshop. Genius is not an individual achievement, but the quality of the society at any given period; in the works of a single school, therefore, practically the same degree of vitality appears everywhere, and the workmanship of individuals is only to be distinguished by varying degrees of skill. In these circumstances it is only natural that the names of craftsmen are not in fact recorded even on the most magnificent works, with a few accidental exceptions; the sequence of styles and of increased or decreased vitality reveals the political and spiritual history not of individuals but of societies.

PREHISTORIC

Palaeolithic and Neolithic.—Rough chipped stone implements have been found abundantly in Southern India. But a great gap, ethnic and cultural, seems to separate them from those of the Neolithic period. Neolithic implements, both chipped and polished, some antedating and some coeval with the knowledge of copper, have been found all over India. They exhibit a great variety of forms, including pygmy types. Most of the forms are identical with those of Western Asia and Europe; but a peculiar chisel-shaped, high-shouldered celt is found in Chota Nāgpur, Assam, and more abundantly in Burma, Indo-China and the Malay Peninsula (see FURTHER INDIA). Indian culture must have had a continuous history from prehistoric times; this must be borne in mind in a discussion of the earlier history of Indian religion and art, especially in connection with the beginnings of sculpture and design.

Prehistoric Painting.—Primitive ruddle paintings have been found in natural caves in various parts of north central India, and have been regarded by some authors as of Neolithic or even

11. Effigies of donors (Āndhra king and queen) verandah of caitya hall at Kārī, late 1st century B.C.

Palaeolithic date. Those from the Mirzapur District in the Vindhya hills, include a representation of a rhinoceros hunt. This animal is now extinct, but may have survived as late as the sixteenth century. The hunters are shown with barbed spears, suggesting certain of the ancient Indian copper weapons.

Cave paintings from the Hoshangābād District are said to include representations of a giraffe. Those from the Kaimūr range

FROM "JOURNAL OF THE ROYAL ASIATIC SOCIETY"

FIG. 2.—CAVE DRAWING, KAIMŪR RANGE

(fig. 2) show stag hunts. Those from Singanpur include an animal rather like a kangaroo; and also some representations of a horse and of deer which present an extraordinary resemblance even in details to the Palaeolithic paintings of Cogul in Spain.

The literature of the subject is cited by Herbert Kühn (see Bibliography), who discusses the Singanpur examples and their resemblance to Spanish drawings.

Those from Hoshangābād are referred to in the Annual Report of the Archaeological Survey of India, 1917-18, Pt. I, p. 25.

Southern India.—In Southern India the Neolithic culture may have lasted until the middle of the first millennium B.C. The south until then had been fairly effectively isolated from the north by the natural barrier of the Vindhyas and the jungles of central India. We find no copper age, but iron directly replaces stone—presumably as the result of intercourse with the then mixed culture of the north, perhaps about 500 B.C. The southern prehistoric antiquities include very numerous slab-built dolmens, and abundant pottery; amongst the last are oblong, short-legged sarcophagi very similar to those found near Baghdad. The use of coracles is another feature characteristic equally of Southern India and the Euphrates valley. No remains of such a highly developed culture as that of the Indus valley have been found; but it is beyond doubt that the South was already highly civilised centuries before the beginning of the Christian era.

Chalcolithic: Indus Valley Culture.—Excavations at Harappa in the Pañjāb and Mohenjo-Daro in Sind have revealed the existence of ancient city sites belonging to a chalcolithic culture, i.e., one in which both stone and copper implements were in use. Of three superimposed cities at Mohenjo-Daro the youngest may be dated about 2700 B.C., the earliest about 3300 B.C. The Harappa site has remains of the same period, and below these are still older strata.

The buildings are of well-burnt brick. Sculptures in alabaster

AFTER "ARCHAEOLOGICAL SURVEY OF INDIA"
FIG. 3.—PREHISTORIC SCULPTURE, INDUS VALLEY CULTURE

and marble include a painted figure of a man, and a much finer bearded head wearing what looks like a wrought metal skull cap decorated in imitation of hair (fig. 3); in terracotta, figurines of a nude goddess with an elaborate headdress, girdle, and the body ornament (*channavira*) characteristic of later Indian art; in terracotta and in faience, admirable figures of animals, including the bull, rhinoceros, dog and cock. All these are sculptures in the round. But the most abundant and not the least remarkable

works of art are the square seals of faience or ivory, which bear in relief figures of animals, usually a bull, elephant or rhinoceros, with a cult object, apparently a wicker crib or manger, and pictographic signs, partly related to early Sumerian forms and even more similar to pre-Sumerian forms found at Kish, but so far undecipherable. Some scholars believe that the later Indian Brāhmī (Sanskrit) script has been developed from this early pictographic type. One seal bears a seated cross-legged figure attended by snake-hooded Nāgas, as in much later, Buddhist, art; another a sacred tree (the *pippala*, *Ficus religiosa*, later known as

a symbol of various deities, particularly the Buddha) with a horned dragon projecting from the trunk (cf. Ward, *Seal Cylinders of Western Asia*, fig. 710); another a row of men bearing totem standards like those of predynastic Egypt. One earlier seal from Harappa represents a tiger hunt.

Amongst personal ornaments are finely wrought gold, silver, and copper gilt jewellery, chank and carnelian beads, faience

FIG. 4.—PREHISTORIC PAINTED POTTERY, TERRACOTTAS AND SCRIPT OF THE INDUS VALLEY CULTURE

advanced geometrical patterns, foliar motifs, and occasional figures of animals. The dark red and black ware has been found abundantly at Nal in Baluchistan, associated with copper implements, also on the Waziristan frontier and in Sistan. The style bears some relation to that of Anau and of Susa II.

When the Indus culture was flourishing the valley was better watered and more wooded than now. The same culture, perhaps in more provincial forms, may have extended to other parts of northern India, over an area reaching from Baluchistan to Kāthiāwār and through Rājputana to the Ganges valley, as in-

AFTER "ARCHAEOLOGICAL SURVEY OF INDIA"

FIG. 5.—SIXTEEN PREHISTORIC SEALS OF THE INDUS VALLEY CULTURE

indicated by the Gungeria hoard and other finds of copper and neolithic implements.

The Indus valley civilisation and culture show close resemblances on the one hand with those of early Sumer and Babylonia (especially with the proto- or pre-Sumerian of Kish), and on the other with that of historic India. Apart from these archaeological evidences, there has gradually accumulated a mass of evidence tending to show that the early Indian and Mesopotamian cultures represent cognate developments. This applies especially to considerations derived from a study of the history of design (particularly in connection with the animal style and architecture), and to the analogies between Babylonian mythology and cult and

those of the Dravidian (Āgamic) tradition in India, such as the use of the same formulae in representing mountains, clouds and water; the motif of animals with long necks interlaced, and of heraldic and fabulous animals generally; the representation on Babylonian seals of dragons with serpentine bodies and human busts, like Indian Nāgas; the cult of the waters connected with the symbol of the flowing vase in Babylonia and the brimming

FIG. 6.—TYPES OF PREHISTORIC PAINTED POTTERY FROM NAL, BALUCHISTAN

vessel or vase of plenty (*pūrṇa kalāśa*) of India, the former significantly spoken of by Heuzy as the "merveilleux symbole qui était comme le Sainte-Graal de l'épopée chaldéenne," and both of importance in connection with the origins of the Grail cult. To these may be added similarities of technical procedure, as in the process of decorating carnelian by calcining and in the similar composition of Indian and Assyrian glass.

Neither the archaeological nor the mythological evidence suggests that either the Mesopotamian or early Indian cultures have been derived from the other, or has borrowed extensively from the other at any one period, but rather that both have developed *in situ*, though not without intercourse and contact, on the common basis of the early chalcolithic culture which in the fifth and fourth millennia B.C. extended over an area extending from the Adriatic to Japan, and can be associated with the dolichocephalic "Mediterranean" races of southern Asia and Europe and attained its fullest development in the great river valleys of the Nile, Euphrates and Tigris, Karun, Helmund, Indus and perhaps the Ganges. According to one not unreasonable conjecture, the original focus of this culture may have been in Armenia, a country rich in metals and possibly the starting point of early race movements across the highlands of Persia in one direction towards Elam and southern Mesopotamia, in the other towards central Asia and India. Many years of work in this comparatively novel field of research will be required before more definite conclusions can be advanced.

Vedic and Pre-Maurya.—It will be assumed that the Āryans entered India from the North-West, about 1500 B.C., and occupying the Pañjāb, had gradually passed on to the Ganges valley. They probably brought with them a knowledge of iron, and a superior breed of horse, and it may have been these advantages that enabled them to subjugate the existing peoples who already possessed cities and forts, and a more developed material civilisation. After the first period of conflict, the Āryans (as with the later invaders, Scythians, Huns and Mughals) ceased to be foreigners, and became Indians: long before 500 B.C., northern India had become the seat of a mixed culture in which, and especially in the art, both as regards its motifs, and its technical achievement, the non-Āryan element predominated. The conquerors had been conquered by the conquered.

Vedic literature, mainly in the relatively later texts, reveals a knowledge of tin, lead, silver, gold and iron, of cotton, silk, linen, and woollen garments, sometimes embroidered, vessels of

AFTER "ARCHAEOLOGICAL SURVEY OF INDIA"

FIG. 7.—PREHISTORIC COPPER IMAGE (?) AND WEAPONS FROM GUNGERIA

gold and silver, iron needles, bedsteads, thrones, turbans, jewelry, earthenware, round and square huts, and storied buildings, and wheeled vehicles. Some or all of these arts may have been known to them before they entered India; but probably the use of bricks, and certainly everything connected with maritime or purely Indian products (chank, ivory, cotton, pearls, indigenous dye-stuffs, etc.) they must have found in India for the first time. The *Sulva Sūtras* show a knowledge of principles now known as those of dynamic symmetry. Vedic culture shows little or no evidence of Babylonian or Semitic connections.

LATER PRE-MAURYA

Few sites likely to yield remains of this period have been adequately excavated. The later strata of Mohenjo-Daro probably come down to 400 B.C. The greatest number of pre-Mauryan antiquities has been obtained at the Bhīr mound, Taxila; most notable are the finely wrought polished sandstone discs, with bands of concentric ornament, in which are found cable, cross and bead, and palmette motifs, the taurine symbol, elephants, fan palms, and the nude goddess.

It is also certain that the cutting and polishing of hard stones, and the technique of glassmaking had attained already in the fourth and fifth centuries B.C. a perfection never afterwards surpassed; and when in the Maurya period we first meet with stone sculptures, we find the surface of the hard stone highly polished. One other important type of early art is represented by the punch-marked coin symbols; these coins were in use from about 600 B.C. to A.D. 100. The marks include some hundreds of types; amongst the commonest are the mountain (usually with three or more peaks—the so-called *caitya* of older numismatists), river or tank with fish, sacred tree, elephant, horse, bull, sun, moon, "caduceus," "taurine"; the lion, rhinoceros, *makara*, and human figure are rarer. No lingam, thunderbolt, foot-marks or stūpa is represented. These signs (*rūpa*), forming an extensive symbolic repertory, appear to have been those of issuing and ratifying authorities. Many of the symbols are those of particular deities; for example, the three-peaked mountain with moon crescent is otherwise known to have been a symbol of Śiva, and so also the bull. Few or none of the marks are exclusively Buddhist. Some are connected with particular cities, and in their day identified the issuing mints.

As regards design the same forms which are found in the reliefs of the Maurya, Śunga, and Āndhra periods were already current during many centuries before the fourth B.C. These forms include meanders, palmettes, vases with flowers, sacred trees, diapers, spirals, frets, twists and the like, animals adorsed or affronted, and fantastic animals of all kinds. Many or all of these characteristic forms are clearly related to, but not identical with, Mesopotamian types, Assyrian or older. They constitute a common ground of early Asiatic, and in India are cognates of the Mesopotamian forms, not late borrowings. The fact that we find them extant only in the stone sculpture when it first appears in the Maurya period is of course no proof of their late origin; some of the most ancient survive most characteristically in quite modern folk-art, and may well have been current during three or four millennia. Thus, the motif of animals with interlacing necks, known in Ceylon as *pūtṭuva*, where it is one of the commonest motifs of the folk art, was already current in Sumerian art of the fourth millennium B.C., and very many other instances of the same kind could be cited.

As regards sculpture, late Vedic literature, in which a large non-Āryan element has been absorbed, affords evidence for the making of images of popular deities in impermanent materials; and it is certain that the earliest known stone figures (after the Indus valley types), viz., the Yakṣas of the Maurya and Śunga periods,

despite their retention of primitive qualities (frontality, etc.), are not first efforts in any sense; they represent an already advanced stage in stylistic and technical development. We have also the evidence of pre-Maurya terracottas representing the nude goddess and some other types. The latter are of very great importance for the history of art, for though they belong to a stylistic cycle older than that of the stone sculpture, and are still too little known, they provide connecting links between the oldest Indo-Sumerian art and that of the historical period, in style, technique, and costume. In their sense of the inseparable connection of beauty and fruitfulness, and in details of ornament (the body ornament later known as the *chamavira*, and the broad auspicious girdle, *mekhala*) as well as in some facial types, they connect with the earliest sculptures in stone.

MAURYA, ŚUNGA AND EARLY ĀNDHRA PERIODS

Maurya: Aśoka.—With the Maurya period, and especially the reign of Aśoka, we meet for the first time with sculptural and architectural monuments in stone. These fall more or less definitely into two groups, (1) the court art of Aśoka, and (2) the popular and perhaps more purely native art. The chief monuments of the court art are the remains of the great palace at Pāṭali-putra (Patna), and the monolithic pillars on which Aśoka's well-known edicts are inscribed. The edict pillars, six in number, distributed over an area including Meerut, Allahābād, Benares, and the Nepal terai, have round polished monolithic shafts and are provided with elaborate capitals consisting of a lotus "bell," an abacus decorated with geese, palmettos or Buddhist symbols, and a crowning sculpture in the round consisting of one or more animals; they average from forty to fifty feet in height. The finest has been excavated at Sārṇāth, the old "Deer park" at Benares, where first "Turning of the Wheel of the Law" (the Buddha's first sermon) took place. Here there are four addorsed lions support-

were maintained between the Maurya and Seleucid houses. The problem, however, is far from simple. All that is beyond doubt novel at this period is the use of stone to a limited extent for architectural purposes, and probably the use of stone for large sculpture. Nor can the Maurya period, with its invaluable but very imperfect record be considered alone; early Indian art as a whole and the folk art up to the present day bear an intimate relation to Western Asiatic art. This relation is more obviously Babylonian-Assyrian than Persepolitan. Indian bell capitals, for example, are very different from those of Persia. Indian shafts are smooth or octagonal, and monolithic; Persian fluted and segmented. The use of animal standards as symbols of deities is at once Indian, Chaldaean and Assyrian, but not Achaemenid or Seleucid. The so-called Persepolitan capital with addorsed bulls (often horses, elephants or lions) again is so widely distributed and so much an integral part of the whole architectural style in the 2nd century, that it could hardly have been introduced only a century earlier. So too with the civil architecture represented on the reliefs, showing walled cities with towers, and battlements like those of Assyria, with the mythical monsters, and with the elements of the decoration; in all the relationship to Western Asia is conspicuous, but the individual character is equally unmistakable. Nor is it possible to suppose that no art of any kind existed in India before Aśoka; or that there existed some different sort of art just before Aśoka, of which no trace can be found in the abundant reliefs just after him. Thus Maurya and Śunga art directly continue the traditions of pre-Maurya art; Indian and early Persian art are both late phases of a tradition common to all Western Asia.

The early Indian stone sculpture in the round of Maurya and Śunga date is represented by a number of colossal figures in royal costume, apparently statues of independent or attendant Yakṣas and Yakṣis, two of these being found at Pārkhām, near Barodā (Plate X., fig. 20) and at Besnagar, one at Deoriyā near Allahābād, one in Mathurā, and three at Patna; all are in sandstone, and some are polished. The figures are distinguished by great mass and volume. There is no conscious effort for grace, but a statement of an ideal concept in a technique that is still primitive; for the form is frontally conceived, and the transitions from one plane to another are somewhat abrupt. The style achieves its perfection some centuries later in a Buddha figure set up at Sārṇāth.

To the same school of art belong the reliefs of the early vihāra (monastery) at Bhājā,—this is apparent in their volume, and in details of the costume, particularly the enormous turbans, and the pearl-fringed bracelets, which last are found also on some early Śunga terracottas. One of the most remarkable of these reliefs seems to represent Indra, seated on his cloud-elephant Airāvata. Sacred trees (*caitya-vṛkṣas*) guarded by railings and adorned with garlands and umbrellas, are to be seen, and on one side a horse-headed Yakṣi and a man, perhaps with reference to the *Padakusalamānava Jātaka*. On the opposite side of the doorway, which divides what are evidently two parts of a single grandiose conception of earth and sky, is represented the Sun in a four-horsed chariot.

From this time onwards the history of Indian sculpture is richly documented. The great stūpa of Bharhut (175-150 B.C.), of which the extant remains are now all in Calcutta, had an elaborately decorated railing (*vedikā*) and gateways (*torāṇa*). The rail coping bears a continuous floral meander, the flowers and leaves being partly vegetative, partly consisting of jewellery; in the interspaces of the meander are represented many of the Buddhist Jātakas, and other edifying legends. The railing medallions are developed as expanded lotus flowers, or occupied by Jātaka subjects or scenes from the life of Buddha. On the upright pillars of the gateways and some of the railing pillars are found representations of various devatās, Yakṣas and Yakṣis, many of which are provided with inscriptions recording their names, as for example, Kubera; thus Buddhism made use of the popular divinities, as guardians and worshippers. The reliefs are all more or less compressed between the surface plane and that of the background, lacking equally the plastic volume of the Bhājā types and the

ing a Wheel (the *Dharmacakra*, Wheel of the Law and of Dominion); the abacus is decorated with four smaller wheels, and a bull, lion, elephant and horse. Other pillars bear a single lion, a bull or an elephant. The naturalistic treatment of these animals, the technical accomplishment of the work and the fact that this is evidently a stylistically late art all distinguish these sculptures from the contemporary religious sculptures to be referred to below, and it has been argued that the court art of Aśoka owes much to western sources, and even that it was produced by imported craftsmen: it is certain that close and friendly relations

technically more advanced relief of Sāñcī; but the costumes, though modified, are closely related to those of Bhājā. The various decorative motifs, floral and geometrical, are indicative of a highly evolved art. Of the same date are some of the railing pillars of Stupa II. at Sāñcī, and the remains of early sculptured walls (*pākāra*) at Jagayyapeṭa and Amarāvati.

Nearly contemporary with the Bharhut stupa, are the excavated monasteries of Udayagiri and Khandagiri in Oṛissā. The best sculptures are reliefs forming a frieze in the upper storey of the Rāñi Gumphā; the subject, which includes the hunting of a winged deer as a part, has not been identified. The monasteries here are, so far as can be determined, all Jaina; but many of the motifs familiar to Buddhist art, e.g., the Lustration of Śrī-hakṣmī, and the Sun drawn in a four-horsed chariot, are found. Above the arches of the cell doors are found three-headed serpents (Nāgas), and below the frieze a series of small Garuḍa brackets, both features that are later on extensively developed in Khmer art.

Prior to the Śuṅga period the major Indian deities seem to have been represented mainly or exclusively by symbols. As Aśoka speaks of engraving edicts on already existing columns it is possible that the Mauryan bull and elephant capitals were originally erected in honour of Śiva and Indra. Garuḍa and *makara* standards of Śuṅga date at Besnagar refer to Viṣṇu and Kāmādeva, the fan palm capitals perhaps to Baladeva. Śiva is represented on early coins by a bull, or a mountain of three peaks surmounted by a crescent; later, in the Kuṣāna period he appears in person together with the bull and other symbols; Indra and Agni appear on the coins of the Pāñcālas in the 2nd century B.C.; the *abhiṣekha* of Śrī on those of Azilises in the first (as well as on the earlier Bharhut reliefs and on terracottas), other forms of Śrī on coins of Amoghahūti. Indra and Brahmā are freely represented in Buddhist art at Bharhut and Sāñcī wherever the narrative requires; the former with his *vajra* (thunderbolt), and a vessel containing the "Water of Life," usually, too, with a cylindrical metal headdress (*q.v.*), the first appearance of any kind of crown in Indian art (the original royal headdress is a turban).

Patañjali, commenting on Pāṇini, c. 200 B.C., refers to the public exhibition of images of Śiva, Skanda and Viśākha; and there is evidence enough in the later Brāhmaṇas, Law Books, Epics, and Buddhist and Jaina literature to show that the use of images and temples (*qq.v.*) had come into general prominence from about 400 B.C. onwards. Probably the oldest surviving anthropomorphic representation of a deity, forming a cult image, is that of Śiva on the Paraśurāmeśvara līṅgam, from Guḍimallam in Eastern India a little above Madras; here the deity stands on a dwarf Yakṣa vehicle, and in this respect and stylistically, though more developed, recalls the Kubera of Bharhut. This early figure of Śiva is a great and powerful work, fortunately preserved from a period when a majority of Hindu images were still made of wood or clay. There is an interesting, though later, reference to such images in the *Divyāvadāna*, where Upagupta, worshipping an appearance of the Buddha created by Māra explains that he is bowing, not to the object before him, but to the Master himself, "just as people venerating images of Gods do not revere the clay, but the immortal ones represented by them."

The most perfectly preserved Buddhist monument in India is the great stūpa at Sāñcī in Bhopal State. Enclosed and hidden within it is an earlier brick stūpa dating from the time of Aśoka, but the stūpa itself as enlarged and cased with masonry dates from the second century B.C., the plain railing from the same time, and the gateways from the first half of the first century B.C. Two other stūpas with their railings in whole or part are to be dated in the second century B.C.

The reliefs of the great gateways (*torāṇas*) of the main stūpa, occurring on the upright pillars and on the horizontal architraves illustrate Buddhist legends, including Jātakas and scenes from the Buddha's ultimate incarnation. They are executed with a delicacy and wealth of detail suggestive of ivory carvings, and indeed a votive inscription records that some were carried out "by the ivory workers of Bhilsā." Apart from their original intention they afford a veritable encyclopedia of manners, weapons, decoration

and symbolism. At the base of the upright pillars are very beautiful figures of guardian Yakṣas; and the architrave brackets are Yakṣis represented as dryads clinging to their trees and leaning outwards. Several of the smaller panels illustrate the Lustration of Śrī, an old and popular goddess of fortune, standing or seated on a lotus, which rises from a jar of plenty (*puṇṇa-ghaṭa*), and laved by two cloud-elephants holding in their trunks inverted jars from which proceed streams of water; other panels in corresponding positions represent the jar of plenty with its lotuses, but without a figure, are probably symbols of the same divinity. On the tops of the uppermost architraves are Buddhist symbols guarded by *caurī*-bearing Yakṣas.

Just as at Bharhut, and in early Indian art generally, in the scenes from the Buddha's life, though they tell their story with perfect clarity, the Buddha himself is never represented in human form, but only by symbols, footprints (*pāduka*), and umbrella (*chatra*), or wheel (*cakra*), or tree. These symbols indicate the presence of the Buddha wherever required in the representation, and some refer to specific episodes in the life, including most of those which are afterwards grouped together in panels illustrating the Four (or Eight) Great Events. Thus, the Wheel designates the First Preaching of the Law; the sacred tree (*Bodhi-druma*) with its altar or railing, the Great Enlightenment. Where the tree is represented with guardian Yakṣas on either hand, we recognize the prototype of the later Buddha triads, where the Buddha is seated between a pair of attendant Bodhisattvas; for there is no doubt that the principal Bodhisattvas, especially Padmapāṇi (Avalokiteśvara) and Vajrapāṇi were originally guardian Yakṣas.

Further, the art of Sāñcī, though Buddhist in theme, is scarcely Buddhistic in content; the legends illustrated are always edifying, but the manner of treating them and the feeling for the human form are far from ascetic or introspective. And this becomes especially evident in connection with the accessory figures, such as the dryads, filled as they are with the abundance and joy of life.

A very important school flourished at Mathura from the second century B.C. to the sixth A.D. The early fragments are in a manner closely related to that of Bharhut. More important are those which cover the period of transition from the old aniconic to the later anthropomorphic representation of the Buddha figure: these are of Kuṣāna, and perhaps somewhat earlier (Indo-Parthian or Kṣātrāpa) date and will be discussed below.

KUṢĀNA

Assuming the date of A.D. 120 for the accession of Kaniska, we can safely say that the first century and a half of the Christian era represents the most critical period in the history of art in India, the second to the fourth century that of highest achievement. For the earlier period, and only to a somewhat lesser extent the later, the prolific school of Mathurā is of primary importance, for here were evolved types that can be traced in all the later development. While confining ourselves in the main to a study of the Buddhist art at this time, we must recollect that at all times "Buddhist India" was equally and at the same time a Hindu India; the so-called Hindu renaissance of the Gupta period does not represent a reaction, but rather the flowering and culmination of a previous development. So far as cult and literature are concerned, this is self-evident; as regards the art, while Buddhist monuments are at first much more abundant and magnificent, this probably means that Hindu cults adhered longer to the use of impermanent materials such as wood and clay for buildings and images, as in southern India up to the beginning of the seventh century. Thus all the coins of Kadphises II. (c. A.D. 90-110) bear the effigy of Śiva, and amongst the many deities represented on the coins of Kaniska and Huviṣka the figure of the Buddha is exceptional, while that of Śiva is abundant. There is certainly no sound basis for the view that Hindu architecture and art are modelled on those of the Buddhists; the style and technical achievement of Indian art can never at any stage be described in sectarian terms, but only in terms of chronology and geography.

Indian Buddha Type.—Within the first century and a half of the Christian era the Buddha figure for the first time replaces the old symbols, which nevertheless remain in use both

in Gandhāra and at Amarāvati considerably later. Images of other deities had long existed, and the influence of current devotional tendencies acting on Buddhism and Jainism must have led to a similar development. The fixing of a date for the earliest images of Buddhas or Jinas is more difficult. Palaeographic evidence would seem to place those of Jinas from the Kankālī Tīlā, Mathurā, as early as the middle of the first century. The only certain date for an early image of Buddha is that of the colossal image set up by Friar Bala at Sārnāth in the third year of Kaniṣka's reign, thus A.D. 123. This Buddha type is distinguished by certain peculiarities not found after the Kuṣāna period (with one exception of fifth century date), and rarely met with even after the middle of the second century. The seated figure is always on a lion throne, never on a lotus. Many other images, both standing and seated, in the same vigorous style derived from that of the early Yakṣa types, have been found at Mathurā, or are of Mathurā manufacture, exported and set up at sacred sites widely distributed in the Pañjāb and Ganges valley.

The earliest Buddha (and Jina) type shows the ends of the shorn hair forming a single conical spiral on the top of the head, bearing no resemblance to the *uṣṇiṣa* in the sense of a cranial protuberance such as characterises the Buddha figure at Amarāvati, in the Gupta period, and subsequently, both within and beyond the boundaries of India proper. When this cranial protuberance appears, it together with the rest of the head, is covered with innumerable short and tight curls, curling to the right. According to the Buddha legend, the Bodhisattva when first adopting the homeless life of an ascetic, cut off with one stroke of his sword both his long hair and the turban which covered it, when they were received by the gods and worshipped by them as the Great Crest relic (*cūḍā maha*), the remaining hair, two inches in length, curled tightly to the right, and so remained throughout the Buddhas life, never again needing to be shorn. This could have been understood to mean either a single curl or many curls; this ambiguity seems to be reflected in the two varieties of the Buddha type above referred to, the interpretation in the sense of many curls very soon supplanting the other. The question of the cranial protuberance is more involved. As in the case of other images of deities (the Buddha even in his own lifetime is more than man, he is recognized as "God of gods" when, at the Presentation, the Tutelary Yakṣa of the Śākya bows before him, and as the object of a cult he must be called a deity) the Buddha image represents a dogmatic conception; the essential element in this conception is that of the idea of the Mahāpuruṣa (Great Male, also a designation of Viṣṇu) and Cakravartin (Universal Emperor, or alternatively, World-teacher). Buddhist texts take over from Brahmanical sources the lists of physical peculiarities which characterize such a being; for example, the soles of his feet and palms of his hands bear stigmata of the wheel, and there is a tuft of hair (*ūrṇā*) between his eyebrows, and all these peculiarities are commonly found in Buddha images. Most of the other marks are relatively inconspicuous or not externally visible. One is of particular importance for the present enquiry; the infant Bodhisattva is said to be *uṣṇiṣo*, *uṣṇiṣa*-headed. In interpreting this and other of the marks (in all thirty-two major *lakṣaṇas* and eighty minor signs) it should be borne in mind that they must originally have been conceived as characterising an adult. Now *uṣṇiṣa* in early Indian literature is the regular word used for the turban, which headdress is a mark of rank, worn by kings or by others on special occasions. *Uṣṇiṣa*-headed can only mean (1) having a head like a turban or (2) having a turban on his head. Inasmuch as the thirty-two marks really characterise a Cakravartin as an adult being, and as the turban is actually a mark of rank, the latter interpretation is to be preferred, in the sense "destined to wear the turban," as we have to do with a child. But as the Bodhisattva became, not a Universal Emperor, but a Buddha, and abandoned his turban and long hair, he had to be, as always, represented (with the exception of certain crowned types which may be Dhyāni Buddhas) as bareheaded. In the early Mathurā figures the problem seems to be ignored. It would appear that after these had been for some time in vogue a necessity was felt to embody the *uṣṇiṣo* idea

in the canonical image, and this was done by making the *uṣṇiṣa* a cranial protuberance, and this took place (in the second century A.D.) at the same time that many curls were substituted for one.

The figure of Indra as Sānti, of the Bodhgayā railing (c. 100 B.C.), has the hair represented in schematic curls, with the appearance of a cranial protuberance, and many representations of Yakṣas as having curly hair; the existence of such prototypes may have contributed to the formation of the Buddha image as ultimately accepted.

Next in abundance to the Buddhist remains are those of the Jinas. The site of the Vohra stūpa, founded in the second century B.C., has yielded figures of Jinas, similar to those of the Buddha, except that in the case of Paśvanātha the Jina's head is sheltered by the hoods of a Nāga rising above it. Highly characteristic for Jaina art are the *āyāgaḥaṭas* or votive slabs bearing reliefs representing stūpas, or elaborate designs, with a central seated Jina, quadruple *trīśūla* symbol, and the Eight Auspicious Symbols.

Figures of Hindu deities are found chiefly on the coins of Gondophares, Kadphises I. and II., Kaniṣka, Huviṣka, Vāsudeva. The variety of types of Śiva is especially noticeable. Many-armed and many-headed types appear for the first time in the second century; Śiva is then four-armed, and sometimes three-headed (Maheśa), the latter type being evidently very popular, as it spread quite early to Gandhāra and Central Asia, where it occurs in sculpture and painting. Many of the Yaudheya coins bear a six-headed Skanda. On coins of Kaniṣka a very great variety of deities appears, Greek, Zoroastrian, and Indian. The figure of the running Wind god is original and remarkable; it corresponds to that of his son Hanuman, the monkey god, the servant and worshipper of Rāma, in later sculpture and painting. The Buddha appears first on a coin from Ujjain, then in three types on coins of Kaniṣka.

Jaina and Brahmanical Types.—Many detached railing pillars, pediments, door jambs, architraves, lintels, and brackets excavated at Mathurā and dateable for the most part in the first or second century A.D. are proved by the subject matter of their reliefs to be derived from Buddhist or Jaina stūpas, temples, or monasteries. The Brahmanical temple site at Māt has yielded the famous inscribed statue of Kaniṣka, and other royal effigies. We learn of a *devakula* (temple) of the Nāga Dadhikarṇṇa.

GANDHĀRA

Graeco-Buddhist Sculpture.—The prolific Graeco-Buddhist school of the North-West Frontier (Afghanistan and part of the Pañjāb, including Peshāwar and the site of Taxila) has always attracted the attention of archaeologists. Its subjects, as in Indian Buddhist art, are drawn from the Buddha legend, and we meet with countless images of Buddhas and Bodhisattvas, and of other deities such as the Tutelary Pair, Kubera and Hārītī. The influence of the school is widely extended in Central Asia, affecting China, Korea, and Japan to a less degree.

Very few Gandhāra images bear dates, and no one of these dates is in a known era. According to some interpretations these dates indicate a beginning of the art in the first century B.C. But at Taxila, where excavations have been scientifically conducted, Graeco-Buddhist art is entirely absent from the Scytho-Parthian and very early Kuṣāna levels of the city of Sirkap, and only appears a little before the time of Kaniṣka. In any case the period of greatest production coincides with the reigns of Kaniṣka (acc. A.D. 120) and Huviṣka, in the second century A.D. Grünwedel dates Kaniṣka A.D. 78 and makes the Gandhāra school begin in the second century, thus later than the establishment of the Mathurā type. But, the Buddha image may have come into use, as the result of a common religious necessity, simultaneously in both areas; though the priority for Gandhāra, even if established, would not affect the fact that the Indian Buddha image of the Gupta period is derived directly from the early Mathurā type, as this in turn is derived from that of the Yakṣa types of the earliest Indian school. It may be safely said that the influence of the Graeco-Buddhist school in India has been much exaggerated.

The Gandhāran type differs from Indian types in more than one way; iconographically by a different treatment of the hair, and in the seat, which is in Gandhāra nearly always a lotus, in India is at first always a lion throne, despite the fact that the lotus seat as a divine symbol had long been known. Stylistically, the differences are more profound. Gandhāran is "late," and belongs to an age of aesthetic decadence in its own cycle; it is naturalistic by intention, although its appearance of realism is no longer based on any structural reality; its graces are deliberate and languid; the solid folds of the drapery are carefully represented. The Indian type has still all the energy and volume of primitive art; it makes no pretensions to grace, is without naturalistic intention, and the drapery is schematic and clinging. It would hardly be possible to juxtapose two contemporary styles more distinct in kind.

The Gandhāran art in its own environment is gradually Indianised, and its productivity ends with the Hūna invasions of the fifth century.

LATER ĀNDHRA

School of Amarāvati.—The reliefs of Amarāvati, dating from the close of the second century A.D., once adorned a great stūpa, with the largest and most richly decorated stone railing ever constructed surrounding it. This stūpa was one of numerous Buddhist monuments erected or enlarged by the later Āndhra kings in the Kistna-Godāverī delta, their seat of government. This later Āndhra art is the most intimate and most enchanting of any in India. Just as in literature, epic form is passing into "poetry" (*kāvya*), so here for the first time sculpture is becoming "art."

The subject matter of the reliefs has not changed; the principal compositions represent *Jātakas* and scenes from the life of Buddha (in accordance with traditions earlier than that of the *Lalitā Vistara*). Vital moments of the Buddha epic are now more dramatically and emotionally conceived; the gestures, especially those of women, possess a peculiar poignancy, reminding us of such contemporary Buddhist literature as the *Bodhicaryāvatāra* and the work of Sānti Deva. This poignancy, survives indeed at Ajanṭā, and Gupta art is very closely related to that of the Āndhras in the third century; but very soon, in so far as it belongs to life, it passes into the formalities of chivalry, and in so far as it belongs to art, into deliberate emphasis and even exaggeration. The same is true of the decorative motifs; a sense of organisation already long perfected is here applied to traditional motifs, with an inimitable delicacy and firmness. The ornament, in fact, is of precisely the same quality, and has the same value as the reliefs with figures. An art which had been entirely corporeal now acquires a spiritual content, becoming Buddhist in a more than formal sense.

As regards the Buddha figure at Amarāvati, and the similar early types found in Ceylon, the use of a cult image is still new, and the figure therefore retains more of the austerity and massive individuality of primitive art than in the reliefs and ornament.

GUPTA

A.D. 320-c. 600.—In early Gupta art the spirit is still at the height of its vitality, but maturer, more intellectually conscious, more introspective; at the same time the expression is less reserved. Gupta art is characteristically logical; sophisticated, gracious and sensuous. Early Gupta art is important in the history of Indian art, as representing a completely unified national style within the limits of India proper, and at the same time embodying the types of which the influence predominates in the south-eastern and far-eastern developments of Indian iconography and architecture. The Gupta style is unmistakably recognizable in the sculpture and architecture of fifth to seventh century date in Burma, Siam and Cambodia. (*See FURTHER INDIA AND INDONESIA.*)

The Buddha figure of the Gupta period is characterised by its definition and refinement; the diaphanous robe, covering one or both shoulders clings closely to the body, almost without folds ("wet drapery"); the hair is invariably arranged in short curls, the *uṣṇīṣa* is indicated as a cranial protuberance, and there is a

lotus or lion pedestal, usually with figures of donors. The finest examples have been found at Sārnāth and Mathurā, in relief at Ajanṭā. One colossal copper figure, weighing over a ton, found at Sultāngāñj is now in the Birmingham Museum and Art Gallery. Brahmanical sculpture is represented by *mukha-līngams* (Śiva) of admirable workmanship from Bhumara, Khoh and other sites in Bundelkhaṇḍ; reliefs of Viṣṇu, Narasiṃha, and Durgā, and the magnificent Varāha Avatār at Udayagiri, Gwalior; *Rāmāyaṇa* scenes from the basement of the late Gupta temple at Deogarh; sculptures of the Rāmeśvara cave, Elūrā; and the stucco reliefs of the Mañiyār Maṭha at Rājagṛha.

The famous paintings of Ajanṭā and Bāgh, all on the walls of excavated Buddhist temples and monasteries, the so-called "Caves," belong for the most part, to the Gupta period, though none appear to be immediate products of Gupta patronage. Those of Caves IX. and X. date about the beginning of the Christian era or even earlier, those of Caves XVI. and XVII. about A.D. 500, those of Cave XIX. about the middle of the sixth century; those of Caves I. and II. date from the seventh century, and thus Early Mediaeval. The subjects are all Buddhist, representing *Jātakas* and scenes from the Life of Buddha, with the popular mythology of Yakṣas and Nāgas as incorporated in Buddhism.

EARLY MEDIAEVAL

Harṣa: Nālandā.—Harṣavardhana in the first half of the seventh century revived the glories of the diminished Gupta empire. He may be regarded as responsible for the restoration of the great monastery at Nālandā, and for the transition from Gupta to mediaeval art in Magadha generally. He also took possession of the Valabhī kingdoms of Kāthiāwār and Gujārāt; but was defeated by the Cālukyan king Pulakeśin II. A more detailed account can be given of early mediaeval art in the Dekkhan and the far south.

Pallavas.—The Pallavas originated in the Kistna-Godāverī area, inheriting the artistic tradition of the eastern Āndhras. Forced to move southward about 600, the sudden appearance of architecture and sculpture in stone is due to the accomplished Mahendravarman I. (600-625); we know from one of his inscriptions that up to this time structural temples had been built of brick, timber, copper and mortar, and the implied absence of stone construction corresponds to and explains the appearance of Pallava art already fully evolved in the 7th century. All the sculpture at Māmallapuram, including that of the excavated and monolithic temples (the "Seven Pagodas"), and also the great rock-cut relief representing Bhagiratha's penance and the Descent of the Ganges belong to the first half of the 7th century. The sculpture here, Paurāṇik in theme, for the Pallavas were Hindu kings, is of a very high order. In the early 8th century the sculpture develops in more strictly architectural application, in connection with the great structural temples at the Pallava capital, Kāñcīpuram, passing in the 9th into that of the Coḷa period. Painting which has been assigned to the time of Mahendravarman I. has been found in a Jaina excavation at Pudokottai.

Early Cālukyan.—Some temples with sculptures at Bādāmi antedate Pulakeśin I. (550-566), founder of the dynasty. Later artistic history shows a mixture of northern and southern elements, but is mainly a development of Pallava forms. The Brahmanical caves at Bādāmi and Aihole (especially Cave III., date A.D. 578) contain a series of large and important reliefs illustrating Paurāṇik mythology and legend. Worthy of special mention also are the sculptured roofing slabs from Aihole, dating from the early 7th century, and now in the Prince of Wales Museum, Bombay. The Virūpākṣa, most important of the structural temples at Pattadakal was built about 740, probably by architects and masons brought from Kāñcīpuram, and shows a corresponding Pallava character in the sculptured reliefs. The Buddhist caves at Aurangābād, dating from the late 6th and early 7th century contain many important figures. At Elūrā, the Das Avatāra, Rāvaṇa kā Khāi, Dhumar Leṇā and Rāmeśvara caves appear to range from 650 to 750.

Rāṣṭrakūṭa.—The Rāṣṭrakūṭas succeeded the Cālukyas in the Western Dekkhan in 753. Their most important monuments are at Elūrā and Elephanta; the latter are easily accessible in an

INDIAN PAINTINGS OF THE RAJPUT SCHOOL

These paintings, executed in the late 16th and early 17th centuries, are done in brilliant tempera colours on a paper surface and show no trace of Persian or Mughal influence. The one on the upper left illustrates an episode of the Krishna cycles showing Radha, supported by two companions, keeping an appointment with Krishna, who is seated at the trysting place in a walled orchard. The three other paintings illustrate Ragas and Raginis, or musical modes, depicting emotional situations corresponding to the content of the music in accordance with established conventions

afternoon from Bombay. At Elūrā the famous rock cut Kailāsa-nātha temple, a huge and complete monolithic shrine excavated in the side of the hill, is in a purely Dravidian style, immediately derived from that of the Virūpākṣa at Bādāmī; of the very numerous sculptures illustrating Śaiva subjects, the finest represents Śiva and Pārvatī seated on Mt. Kailāsa, with Rāvaṇa imprisoned within the mountain below, endeavouring to cast it down, and succeeding in causing a tremor; this, and the Varāha Avatār of Udayagiri, above alluded to, are the finest examples of reliefs which deal with what may be described as cosmic or geotectonic themes. Remains of painting on the ceiling of the porch of the upper storey are of two periods, in part no doubt of the eighth century and nearly contemporary with the actual shrine; these are the oldest surviving Brahmanical frescoes, but literary references show that painting had been practised both as a religious and secular art from time immemorial.

At Elephanta, the most famous, and perfectly preserved sculpture is a colossal relief in the main excavation, a three-headed bust, which has often, though incorrectly been called a Trimūrti; it is actually an icon of Śiva in the form known as Maheśa, and many other examples exist, of which one of the best is a later relief in the Pennsylvania University Museum.

Kashmīr.—The old town of Vijrabrūr has yielded early sculptures in which the influence of the Graeco-Buddhist art of Gandhāra is still apparent; the most interesting of these are representations of the goddess of Fortune, Lakṣmī, seated with a cornucopia, and these types can be followed well into the mediaeval time, gradually becoming completely Indianised. The remains of a tiled cock-pit of about the 5th century at Harvan are unique; the devices on the moulded tiles represent men seated, and in balconies; equestrian archers in chain armour, deer, fighting cocks, lotuses, and a fleur-de-lys motif; in technique they recall the so-called Han but probably later grave-tiles of China.

The Vāntipor temple sites of early 9th century date have yielded small and admirably executed stone figures of Viṣṇu in a style peculiar to Kashmīr and the neighbouring States of Cambā and Kuḷū, and with these there appear also Śiva types, including a three-headed Maheśa, and an Ardhanārīśvara. Similar Vaiṣṇava images of brass inlaid with silver and copper have been found in Kuḷū, together with a Buddha image in the same technique, but of earlier (late Gupta) date. Buddhist "bronzes" found in Kashmīr, and ranging from the 6th to the 11th century, show that Buddhism survived to a late date, although it had already declined by the end of the 8th century, all the foundations of Avantivarman in the 9th being Brahmanical. The stone sculpture architecturally associated with the great temples in Kashmīr is unfortunately almost all in a ruined state.

MEDIAEVAL (FROM ABOUT 850 ONWARDS)

The Mediaeval art again falls into three main divisions, corresponding to the geographical classification of the architecture as *Nāgara* (Northern and Eastern), *Vesara* (South Central and Western) and *Drāviḍa* (Southern). The character of Indian art has now definitely changed and hardened; the sculpture is no longer distinguished by plastic volume, but has acquired a linear character; that is, the form appears to be conceived from the standpoint of outline, and all the features are sharply defined; its application is primarily architectural, and one might say decorative, were it not for the fact that it retains a precise significance in all its details; its forms are more complicated, partly because the theological development has brought in a greater variety of many-armed forms (these appeared first in the second century, and are already common in Early Mediaeval work), and partly because of the tendency, innate in all late art, towards great intricacy and elaboration of detail, and an overvaluation of merely technical skill, displayed as an end in itself.

Northern and Eastern.—The main schools are those of Bihar and Bengal (Pāla Dynasty); Orissā; and Bundelkhand and Rajputana. Under the Pālas (750–1200) the main centre of production was at the important monastery and university of Nālandā in Bihar. The characteristic Buddhist images, together with Buddhist and Brahmanical examples from other sites in Bihar and Bengal are executed with the utmost technical proficiency in

a kind of black slate, and are represented in all large collections; and in recent years very numerous and exquisitely made copper images have been excavated here or found elsewhere in Bengal (Rangpur and Chittagong). The themes are at first Buddhist, but the Buddhism is greatly mixed with Hindu elements, and acquires as time passes a more and more Tāntrik character. The names of two painters and sculptors, Dhīmān and Bitpālo, are mentioned by the historian Tārānātha as having been masters in the Eastern School in the 9th century. The Bihār school exercised a powerful iconographic and stylistic influence on Nepal, Tibet, Burma and Java and Sumatra. Not only sculpture, but also painting was practised; a number of Buddhist palmleaf manuscripts from Bengal and Nepal, with painted wooden covers, and illustrations in the text have been preserved from the 11th and 12th centuries. The style is most closely related on the one hand to the slightly later painting of the Gujarātī school, and on the other to the contemporary frescoes of Burma (Pagan). The Pāla school of painting in the 12th century was known even to the Chinese.

Sculpture in Orissā is typically Brahmanical, and occurs in connection with the series of great temples at Bhuvaneśvara, Koṇārak, Purī, etc., ranging in date from the 8th to the 13th century. The monumental horses and elephants, and the erotic architectural sculptures of the Sun Temple at Koṇārak are especially noteworthy.

Bundelkhand and Rajputana.—The magnificent temples of Khajurāho are literally covered with Brahmanical sculpture in a hard creamy sandstone; and isolated fine examples have been found at Mahoba, another Candela capital. Jaina sculptures too occur in abundance, but Buddhist works are relatively rare. To enumerate the sculpture in Rajputana would be impossible; there is much of excellent quality.

South Central and Western.—An enormous revival of building and sculpture took place in the Dekkhan under the later Čālukyas after 973, the Hoysālas of Mysore in the 12th and 13th centuries, and in Gujarāt under the related Solāṅki dynasty (10th to 15th century). The sculpture of the Dekkhan and Mysore is executed in a fine-grained dark chloritic schist, which is comparatively soft when first quarried, and lends itself to an unlimited elaboration of detail more appropriate to metal-work than stone. Almost all the work is of architectural application, and unbelievably rich in quantity and detail. Especially characteristic are the elevated temple basements, with tier upon tier of sculptured friezes, and the huge turned cylindrical pillars of the porches, with luxuriously developed bracket figures of dancers. In Mysore, Belūr, Halebid, Doḍḍa Gadavalli, Somnāthpur and Śravaṇa Belgola are amongst the most famous sites. At the latter place there is a remarkable monolithic image of Gommateśvara (son of the first of the 24 Jinas of the Jaina mythology); one of the largest freestanding figures in the world, 57 feet in height, this was carved *in situ* for Cāmuṇḍa Rāja in A.D. 981. Another figure at Ilivālā is over 20 feet in height.

In Gujarāt, Kāthiāwār and parts of Rajputana there exists another extensive development in a related style. In Gujarāt proper, most of the temples are in ruins. At Gīrnār, Palitāna and Taranga, Jaina temple cities and places of pilgrimage, there is much sculpture still *in situ*. The most famous and remarkable examples of the style, however, are to be seen at Mt. Ābū (Dilvārā, in southern Rajputana), in the temples of Vimala Shah (c. 1032) and Tejāhpāla (c. 1232); these are domed shrines with pillared halls.

Gujarātī (Jaina) Painting.—A Gujarātī school of manuscript illustration flourished from the 13th to the 17th century, after which it is more or less modified by Mughal and Rajput influences. One manuscript dated 1237 is on palm-leaf, all others are on paper, with earliest date 1427. The majority of the manuscripts are Jaina scriptures, but there is one secular example, a *Vasanta Vilāsa*, dated 1451. Although the colouring is brilliant, the style is really one of pure draughtsmanship; the outline establishes all the facts, and this outline, though very facile and almost careless, is extremely accomplished.

Rajput Painting.—The tradition of mural painting, exterior

and interior, even at the present day survives sporadically all over India; a good deal may still be seen in Rajputana, for example in the Old Palace at Bikāner. Paintings on canvas and illustrated manuscripts are very rare. But as paper gradually came into use, the older methods of painting on walls and panels or cotton cloth were employed on the new material; the technique of Hindu painting on paper is in fact identical with that of the older mural art as seen at Ajañtā and described in the technical treatises. The themes of Rajputa painting are religious (dealing especially with the Kṛṣṇa cycle, but also with Śaiva and Vaiṣṇava mythology in general), Epic (*Mahābhārata* and *Rāmāyaṇa*), lyrical and rhetoric (*Rāg-mālās*), and, less typically, secular (portraiture). The Kṛṣṇa cycle and themes illustrating treatises on rhetoric (classification of heroines, and emotional analysis), given a contemporary environment in court and village life, permit an exquisite delineation of every phase of love. The Epic subjects, especially in early Jammū works, are treated on a large and almost mural scale. Especially characteristic are the sets of illustrations of the *Rāg-mālās*, vernacular poems describing the situations which are appropriate to each of the Rāgas or musical modes; these are usually 36 in number, and each has its particular hour and specific sentiment (see INDIAN MUSIC). Stylistically Rajput paintings can be classified both geographically and in historical sequence. Very few of them show any approximation to the Gujarātī style. The early examples from Rajputana and (or) Bundelkhaṇḍ are most distinctive; here we find a robust analytical method of drawing, an indication rather than a representation of forms, and an intensely brilliant colouring, like that of enamel or stained glass, by which the planes are established. A modified tonality gradually appears, partly due to Mughal influences; but even in the 18th century, when the outline has become more meticulous, the work of Jaipur artists can be recognized by its brilliancy, and by its marvellous decorative treatment, especially of flowers and trees. The earlier Jammū productions too are strongly coloured, while the drawing is more provincial throughout. In some respects the most exquisite, and certainly the most refined, if not the most powerful, phase of Rajput painting is that of the Kāngrā school, developed in the latter half of the 18th century under Raja Śaṁsāra Cand; connected with this school are its offshoot in Tehri-Garhwāl, and its early 19th century secular development in Sikh portraiture. The Kāngrā school declined during the 19th century and is now to all intents and purposes extinct. Related schools existed in Bengal and Orissā. By far the finest collection in the world is to be seen in Boston; other examples are in the Lahore and British Museums, and in private collections.

Ceylon.—The artistic culture of Ceylon is at all times very closely related to that of Southern India, but can be more conveniently treated as a consecutive development. One of the oldest documents is a carnelian seal representing a seated king, probably of the second century B.C., from the Yaṭṭhālā Dāgaba in the south, now in Manchester. It is difficult to say whether any or how much of the sculpture surviving at Anurādhapura dates before the beginning of the Christian era; the greater part in any case belongs to the period ranging from the 1st to the 9th century. Among the finest sculptures in Ceylon, previous to their restoration and virtual destruction by pious Buddhists, were the Buddha figures, and one traditionally known as Duṭṭha Gāmaṇi (r. 1st century B.C.), at the Ruanweli Dāgaba site; the Buddha figures show a close relation with those of Amarāvati and must date from about A.D. 200. Relief sculpture may date back to the first century B.C. or but little later; this applies especially to the Nāga reliefs and formal trees rising from "lucky vases," represented on stelae at the Eastern (so-called Abhayagiriya) and Ruanweli Dāgabas, for these are still in flattened relief, and distinctly related in style to the Sāñcī and early Sārnāth reliefs of the 1st century B.C. The "moonstones" or stone doorsteps of monasteries or palaces are of various dates, and consist of half lotus medallions with friezes of animals (horses, lions, elephants and bulls, or geese carrying floral sprays; the steps above them are flanked by solid balusters (*ālamba bāhu*, *hasti-hasta*) consisting of heads and trunks of elephants, or *mākara* heads spouting vege-

tation; while at each side stand reliefs representing Nāgas, holding "lucky vases" and cornucopiae. The rock-cut reliefs of elephants and a seated sage ("Kapila") at the Isurumuniya Vihāra, the elephant reliefs by the Tissawewa lake are in Pallava style and evidently of 7th century date.

At Poḷonnāruwa, the rock-cut statue traditionally regarded as a representation of Parākrama Bāhu I. (1153-1186) is a magnificent work; not so fine, though impressive in scale and design are the seated and reclining Buddha figures of the Gal Vihāra, where there is also a colossal standing figure of the disciple Ānanda. Some of the brick and stucco figures of the Northern temple are extremely elegant.

There exist colossal Buddha figures of the Poḷonnāruwa period also at Seṣēruwa, Āwkana and Kon Wewa.

A limited number of small bronzes or rather copper images of very high quality have been found in Ceylon. One of the largest is a fine seated Buddha from Badullā, of about 6th century date, but the finest of all are a well-known seated Avalokiteśvara with figures of Vajrapāṇi and Jambhala, of 8th and 9th century date, now in Boston; there is a fair collection of similar figures in the British Museum. Brahmanical bronzes apparently of Cola date have been excavated at Poḷonnāruwa and are now in the Colombo Museum.

Remains of painting have been preserved at a number of sites. There are a few traces of decoration at Anurādhapura, including some figures of dwarf Yakṣas. More remarkable are the Apsarases of the painted rock pockets at Sigiriya, dating from the 5th century, and still in excellent preservation; these are voluptuous female figures, cut off by clouds at the waist in accordance with a characteristic convention, and casting down a rain of flowers upon the mortal world below them. At Hindagala near Kandy there is a fragment of fresco regarded by some as of rather early date, but probably mediaeval. By far the most extensive remains, though now almost destroyed by neglect since their first discovery, are those of the inner walls of the Northern Temple at Poḷonnāruwa; these illustrate *Jātakas*, but can only be inadequately studied in the bad copies exhibited in the Colombo Museum. The Sinhalese chronicles (*Mahāvamsa*) contain innumerable references to painting, but nothing more survives until we come to the 18th century, when Kīrti Śrī Rāja Śimha, one of the last Kandyan kings, restored many shrines in the Kandyan provinces. Mention must also be made of the admirable decorated ceilings of Kelaniya, Kandy, and some other places; these are often masterpieces of design.

During the 19th century little of note in sculpture was produced in Northern India. In Southern India the indigenous tradition has been preserved in greater purity; copper images, sometimes of large size, and little inferior in quality to those of the 17th and 18th centuries are still made, and hereditary craftsmen still work in stone. In the present century a reaction against Western mannerisms has taken place, and especially in Calcutta, where a considerable (Bengal) school of painters is at work, a very large number of pictures, mostly water-colours, has been produced. The pictures are delicate and often very charming, but hardly powerful; the movement is comparable in some respects to that of the Pre-Raphaelites in Europe. Amongst the chief artists who have been or are still at work may be mentioned Gogonen-dronath Tagore, who works mainly in monochrome, and has flirted with Cubism; Nanda Lal Bose; Asit Kumar Haldar, now Principal of the School of Art in Lucknow; Samarandranath Gupta, now Assistant Curator, Pañjāb Museum, Lahore; and many younger men, and some women.

(1926). (A. K. C.)

INDIANAPOLIS, the capital and largest city of Indiana, U.S.A., on the White river, at about the exact geographical centre of the State; a port of entry and the county seat of Marion county. It is on Federal highways 31, 36, 40 and 52; has a municipal airport; and is served by the Baltimore and Ohio, the Big Four, the Chicago, Indianapolis and Louisville, the Erie, the Illinois Central, the Indianapolis Union, the Nickel Plate and the Pennsylvania railways, and by inter-urban trolley and motor-bus lines radiating in every direction. In 1920, when Indianapolis ranked 21st among the cities of the United States, the population was 314,194, of whom 34,678 were negroes and 16,958 were foreign-born white (over half from Germany, Ireland and England). The census bureau estimate for 1928 was 382,000.

Indianapolis is one of the most populous cities in the world not situated on navigable water. Transportation facilities by rail and highway are exceptionally good. The first union railway station in America was built here, and the present Union Depot (vastly enlarged since 1917, when work was begun on the elevation of all the tracks) is one of the most commodious and well-arranged stations in the country. Some 160 mail trains enter and depart daily, and the belt line connecting the several railways carries over 2,000,000 freight cars annually. The traction terminal and the motor-bus terminal are the largest in the country.

The city occupies 49.5 sq.m. on a level plain surrounded by low, gently sloping hills. It has the beauty of wide, well-planned streets, winding streams, trees, lawns, gardens and shrubbery. In the exact centre of the original tract of four "sections," surrounded by a circular park, is the Soldiers' and Sailors' monument. It rises to a height of 284.5 ft. above the street level and is surmounted by a figure of Victory 38 ft. high. An elevator runs to a balcony at the top, which commands a panoramic view of the city and many miles of surrounding country. At the base of the monument are fountains with a capacity of 20,000 gal. per minute. From this central circle four avenues radiate to the four corners of the city. The other streets run at right angles to one another. The main street (Washington) is 120 ft. wide; most of the others, 90 feet. There are 18 public parks, with a total area of 2,544 ac.; 46 playgrounds; and 53 m. of boulevard, including a 60 ft. drive-way on the top of the concrete levee (40 ft. high) which was constructed (1914-16) along the west bank of the White river.

North of the Circle is the World War memorial plaza (constructed at a cost of \$10,000,000), covering five blocks given by city, county and state, and containing, among other public buildings, the national headquarters of the American Legion. The State house, in a square of 8 ac., has a ground area of 2 ac. and a central tower and dome 240 ft. high. Many of the public and business buildings are constructed of the famous Indiana limestone, from the Bedford district in the southern part of the State. North-west of the city is the motor speedway, where races are held annually on Decoration Day (May 30), attracting 150,000 visitors from all parts of the country. The home of James Whitcomb Riley, 528 Lockerbie street, is a literary shrine.

Indianapolis was one of the first cities in America to adopt electric street-lighting. A city-plan commission (1919), and a zoning ordinance, adopted in 1922, outlined a scheme for resi-

dential, commercial and industrial districts. The assessed valuation of property for 1927 was \$666,461.290.

The public school system of the city comprises 83 grade and 4 high schools, and employs over 1,500 teachers. The public library, a beautiful example of Greek architecture, on a site presented by J. W. Riley, contains over 400,000 volumes. The private charitable agencies (about 40) are financed by a joint community fund. There are three daily newspapers: the *News*, established in 1869; the *Star* (1883); and the *Times* (1888).

Indianapolis is the seat of the School of Medicine and the School of Dentistry of Indiana university; of Butler university (chartered 1849), Indiana Central college (1904), the Benjamin Harrison Law school, Indiana Law school, the Indianapolis college of pharmacy, the Teachers college of Indianapolis (a private institution), the John Herron Art institute and school, a private school for stammerers, the School of Printing of the Typothetae of America; of the Central Indiana hospital for the insane, the State schools for the blind and deaf, the State prison for women (the first in the United States, opened in 1873), and (at Clermont, 10 m. out) the State reformatory school for girls, which was a department of the prison until 1899. Ten miles north-east of the centre of the city is Ft. Benjamin Harrison, an important United States army post, named after President Harrison, whose home was in Indianapolis. The State fair grounds and the State fish hatcheries are within the city limits. Around the Indiana university school of medicine has developed one of the important medical centres of the country. The school itself was formed in 1908 by the union of the Indiana Medical college of Purdue university and the earlier medical department of the State university, which together incorporated six institutions founded between 1869 and 1906 at several different points in the State. Its new building (completed 1927?) is on the spacious grounds of the Robert W. Long hospital (completed 1914) which is a part of the school's equipment. Near by is the James Whitcomb Riley Memorial hospital for children, built by private subscription and conveyed to the university on the day it was dedicated (1924); and the William H. Coleman hospital for women (opened 1927), also under the university's management.

The transportation facilities of Indianapolis and its position in the midst of the corn belt, near large coal-fields, and with populous markets in every direction, have combined to make it an important commercial and industrial centre. It has a large trade in grain (\$75,000,000 annually) and its elevators have a capacity of over 1,000,000 bushels. First place is held by automobiles, valued at \$75,000,000 annually. Other important manufactures are automobile accessories, malleable iron, foundry and machine shop products, agricultural implements, sewing machines, railroad cars, upholstery and furniture, cotton and woollen goods, glass, flour, canned vegetables, organs and pianos. The printing and publishing business has an annual output valued at \$16,000,000. In 1925 the aggregate factory output was valued at \$344,924,907. Bank debits in 1926 amounted to \$2,207,379,000. The crops produced within 10 m. of the city are valued at \$500,000,000 a year.

History.—When Indiana was admitted to the Union (1816) Congress gave it four sections of public land for its capital. The commissioners appointed to select the site placed it (1820) almost exactly in the geographical centre of the State, at the cabin of John McCormick, on the White river, in the midst of dense forests and without any means of communication with the rest of the State. A town was laid out in 1821 (the "original mile square," bounded by north, east, south and west streets) and some activity in land speculation followed; but when the seat of government was moved here from Corydon in 1824 there was but a single street and 600 inhabitants. The legislature met in Indianapolis for the first time in 1825. It was incorporated as a town in 1832, with a population of 1,000. The first State capitol was completed in 1836. Some impetus was given to the city's growth by the completion of the National Road, and later, beginning in 1847, by the coming of the railways, but the development was slow until after the Civil War. The city was chartered in 1847, and in the same year a free public school system was inaugurated.

In 1850 the population was only 8,091. By 1860 it had grown to 18,611, and in the following decade it increased to 48,244. In the next 20 years (1870-90), and again between 1890 and 1910, the increase was considerably more than 100%, and in the single decade 1910-20 it amounted to 34%.

In the years following the World War, Indianapolis suffered severely from the domination of State and city politics by the Ku Klux Klan (see INDIANA), until exposure of the methods of the Klan (largely through the initiative of the Indianapolis *Times*) led to a weakening of its power.

Dunne; and P. S. Heath's sketch of Indianapolis in L. P. Powell's *Historic Towns of the Western States* (1901).

INDIAN ARCHITECTURE, like Indian sculpture, is essentially of native origin, belonging to the Drāvidian rather than the Āryan race. The Vedic ritual required neither images nor temples, but the non-Vedic cults, such as those of the dragons (*Nāgas*), the tree-spirits (*Yakṣas*) and the goddesses, may have had permanent shrines with images and wooden temples. References to images and temples begin to appear in the literature from about the 4th century B.C. onwards, and numerous types are represented in the reliefs from the 2nd century B.C. In Hindu worship (*pūjā*, the service of a personal deity with offerings of food, lights, incense, etc., as distinguished from *yajña*, the Vedic sacrificial ritual) the first essential is an altar, with or without a symbol or image, serving to receive offerings of flowers. Such an altar beneath a sacred tree, for example, constitutes a *Yakṣa caitya*. The term *caitya* denotes a shrine of any kind, but has often been used (erroneously) to designate exclusively the *stūpa*. The next step is a god's house (*devālaya*, *devāgāra*, *āyatana*, etc.), a simple roofed enclosure containing the altar and symbol or image.

Origins.—The fundamental elements of temple architecture are indigenous and of great antiquity. Early Indian architecture was almost entirely of wooden construction, and the forms thus established were later closely imitated in brick and stone. The various forms of domed and barrel-vaulted roofs, gabled windows

BY COURTESY OF THE FIELD MUSEUM, CHICAGO

TODA HUT, RESEMBLING A BARREL-VAULTED TEMPLE

and roof ends, pillars and cornices are developed from wooden prototypes; the Toda hut, for example, even at the present day presents a striking likeness to a barrel-vaulted gable-ended temple.

A part of Indian architecture, especially at an early period when the use of impermanent building material was otherwise still general, may be described as monolithic; that is to say, the shrine is excavated in solid rock, either by hollowing out the necessary chambers (so that only the internal architecture is brought into being), or by cutting away the exterior rock so as to leave an entire temple of solid rock. Very remarkable works of both

kinds exist. The former, the cave temple type, is best illustrated by the early Buddhist *caitya* halls (Kārī, Nāsik, Ajaṇṭā, Bāgh, etc.), in which the interior of an apsidal temple of wooden construction is reproduced in stone in every detail, and by such great Hindu excavations as those of Elephanta, near Bombay; the latter by the famous Kailāsanātha at Elura, near Aurangābād, the Maśūr temple in Kāngrā, the "Seven Pagodas" at Māmalla-puram south of Madras and the Veṭṭuvankoyil at Kalugamalai in the far south.

Arches and Domes.—As both the arch and dome were known to the Sumerian builder in the fourth millennium B.C. there is nothing surprising in the fact that both appear in India long before the Mohammedan period, and in fact from the Maurya period onwards. One of the earliest temple types is that of a square or circular domed structure, with a roll cornice below the dome. Structural stone buildings of this kind can be traced back at least to the second century.

Special Forms.—Some special forms characteristic of Buddhist and Jaina usage should be briefly described. The most familiar of these is the stūpa (*tope*, *dāgaba*), an elaboration of the old Indian funeral mound, later carried out in solid masonry, provided with enclosing walls or railings, and decorated with sculptures. The essential parts of the stūpa are the dome (*aṇḍa* or *garbha*), solid but for a small relic-chamber near the ground level in the centre, and inaccessible after completion; one or more platforms, supporting the dome, provided with stairways for access, and serving for circumambulation; a small pavilion (*harmikā*) on the summit, and rising from this a mast (*yaṣṭi*) bearing one or more symbolic umbrellas (*chatrāvālī*); one or more railings (*vedikā*) surrounding the dome or the whole structure. In the earliest types of the Buddhist Stūpa the dome is hemispherical; but a more aspiring type is gradually developed, until we reach such tall pointed forms as that of the beautiful Burmese Shwe Dagon. In some Burmese forms the basement is developed to a great height, and is provided with chapels within its mass, for which an Indian prototype can be cited at Mīrpur Khās in Sind. At Borobudur in Java the basement platforms are seven in number, forming a massive pyramid; this plan in a somewhat simpler form occurs earlier in the Punjāb, Kashmir, and Turkistan. The stūpa is almost exclusively of Buddhist or Jaina significance, and as a symbol represents the death or final release of the great teacher, the Buddha of Mahāvīra, as the case may be.

Highly characteristic, also, are the aisled apsidal churches best known from the early Buddhist rock-cut "*caitya* halls," but also represented by structural examples in brick or stone of Gupta and later date (Ter, Ch�ārālā, Aihole; and in Pallava and later Drāviḍa architecture, where the number of storeys is increased, as the crowning member of a tower).

Another special form peculiar to India is that of the hypaethral tree temple, usually a pillared hall, square or circular, with a gallery and vaulted roof, but open in the centre, and surrounding a sacred tree; nearly a dozen examples are represented in Buddhist reliefs, where the tree is the Bodhi-tree, the symbol of the Buddha's Great Enlightenment, but there is every reason to suppose that the type was a very ancient one, developed in connection with the worship of Yakṣas (*q.v.*), or tree-spirits.

Doorways of early buildings are provided with decorated tympanums, reproducing wooden forms, and with a gable or ogee arch above. Entrances to sacred areas were provided with *torāṇas* (resembling Japanese *torii*, where there may be a genetic connection); these consist of upright pillars bearing one or more architraves, of which the elaborate examples at Sāñcī afford the best instances, though many others are represented in reliefs. Applied, as it were, to a wall surface, the same form may be used in rock-cut or structural shrines (*e.g.*, Nāsik, Cave iii.), the pillars becoming jambs, the lower architrave the lintel, brackets being still represented, though no longer functional. In later southern architecture the gateway of the enclosing walls becomes an immense structural tower, called a *gopuram*, often completely dwarfing the main shrine.

The gable or dormer windows (*Gavākṣa*, *Kūḍu*) which are found to be most characteristic as constructional elements in the

early architecture, and as ornament in the later, have been commonly designated "horseshoe arch," from the form, and "*caitya* window," from the large and conspicuous examples that pierce the façades of the early excavated churches. In many cases the two ends of the arch spring from a pair of *makaras* (crocodiles), situated immediately over the capitals of the supporting pilasters, and constituting a *makara torāṇa*. The summit of the arch is pointed, making it an ogee arch. This dormer arch is not confined to India, but reappears in the earlier architecture of Cambodia and Java. Cusped forms are early developed and survive in Muhammadan usage.

Columns.—Indian columns are of two kinds according to use, either single pillars (*stambha* or *lāt*) bearing a symbol appropriate to the deity of the temple beside which they are placed, or structural pillars (*khambha*) of temples or secular buildings. Both occur in a great variety of form, but as regards the shaft, chamfering and an octagonal section are highly characteristic. All types are monolithic. Capitals, too, are very varied. The typical early form has three members: below, an inverted lotus bell; in the middle, four adorsed animals (generally bulls or lions); and above, a trapezoidal cushion with small corner volutes (Assyrian rather than Greek in character). Typical of later northern mediaeval types is a ribbed cushion capital like an *āmalaka*: this form is perhaps to be connected with that of Viṣṇu's mace. Another common form would be rectangular, but that the lower outer angle is rounded, and sometimes ribbed. A very usual form in mediaeval art is that of the "brimming vase," or jar with overfalling lotus foliage, often developed into arabesque. Brackets, often decorated with figures of Yakṣīs, are characteristic at all times.

Walls.—A sacred structure is usually surrounded by a wall (*prākāra*) or railing (*vedikā*). Such a wall consisting of plain slabs mortised into pilasters has been found in connection with a Vaiṣṇava shrine of Śuṅga date at Besnagar; and others, similar, but sculptured, and of the same period are represented by fragments from Amarāvati and Jagayyapēṭa. The railings of the early Buddhist and Jaina monuments are remarkable; these consist of plinth, upright pillars, cross bars, and coping, evidently based on wooden forms; the best preserved are those of the topes at Sāñcī and that at Bodhgayā, both about 100 B.C.; the most elaborate is that of Amarāvati represented by remains now mostly in the British and Madras Museums.

Influences of Indian Architecture.—The architecture of Farther India and Indonesia is largely of Indian origin, and this is particularly evident in the earlier phases (pre-Khmer, etc.); but the forms appear to be developed from older Indian types, rather than directly imitated from those of the Gupta and Pallava styles. Some Indian architectural forms are recognizable also in Gandhāra, Central Asia, China and Japan. Some others are traceable in European architecture, having passed via Alexandria early in the Christian era to Rome and Spain; these include possibly the loggia, galleries, horseshoe and mixtilinear arches, ogee arch and *cyma reversa*, decorated tympanums and jambs, all of which are to be seen in India, and perhaps also the circular and apsidal plans of domed buildings. For a discussion of these interesting problems see Rivoira, *Moslem architecture*, 1918; Beylié, *L'Architecture hindoue en Extrême-orient*, 1907; Strzygowski, *passim*, and other sources cited in *IIIA*, pp. 20, 149; for China *ib.* p. 53, 152 and Taki, *The Indian type in the temple building of North Wei*, the Kokka, Nos. 356, 357; for Cambodia, Parmentier, *L'Art khmer primitif*.

Technical Literature.—Before proceeding to a description of the architecture of successive periods and styles, it should be mentioned that there exists in India a vast technical literature (known as *śilpa-śāstra*) on the subject. The most important of such treatises has only recently been made accessible by Professor P. K. Acharya (*see Bibliography*). Such technical works date back in part to the Gupta period, perhaps much earlier; the mediaeval compilations are still in use by Indian architects, the *sthāpatis* of modern buildings using either the Sanskrit originals or vernacular versions. No more valuable contribution to the study of architecture as a practical art could be made than a detailed

description of building methods still in use in India. It has been shown that the Indian *śilpa-śāstras* must have been used by Indian architects in Java and Cambodia.

INDUS VALLEY CULTURE TO THE GUPTA PERIOD

Pre-Maurya.—The oldest architectural remains in India are the remains of cities at Mohenjo-Daro and Harappa, dating from the fourth millennium B.C. onwards. Here the buildings are of well-burnt brick, laid in mud or gypsum mortar. They include temples; a sacred tank lined with bitumen, and provided with a drain over six feet high, with a corbel-vaulted roof; and substantially built and well-drained dwelling houses and shops.

The only surviving monuments that have been attributed to the Vedic period and culture are the burial mounds at Lauriyā-Nandargarh, the source of the gold plaque of the nude goddess; and certain very ancient rock-cut tombs in Malabar. The Cyclopean walls of old Rājagṛha are certainly pre-Maurya, but there is no reason to connect them with the Vedas or the Aryans; their character is rather Polynesian than typically Indian.

As with design, so in the case of architecture, there is every reason to suppose that the same forms which are represented so admirably in the reliefs of Bharhut, Sāñci, and Amarāvati were already current during many centuries before the Maurya period. The special forms, indeed, are nearer to those of western Asia of the sixth or seventh century B.C., than they are to those of contemporary Persia, and it can hardly be doubted that they represent the Indian development of a widespread early Asiatic tradition. The forms include storied buildings supported on pillars with volute capitals resting on addorsed animals (bulls or lions), often with pot-shaped bases, and having barrel-vaulted roofs with gabled or arched ends and windows; battlemented brick walls; circular shrines with double-domed roofs; pillared barred-vaulted apsidal temples; hypaethral tree-temples; monasteries, of cells opening onto a central court; burial or memorial mounds (stūpas) on platforms; monolithic pillars; and walls and railings.

Maurya.—The most ancient excavated cave shrines, those of the Barābar Hills, which are finely polished, date from the time of Aśoka. The entrance façade of the Lomas Rṣi [Rishi] cave is the earliest example of a decorated tympanum, with ogee arch, finial, curved beams, and resting on sloping jambs, all in imitation of purely wooden forms.

The remains of Aśoka's capital at Pāṭaliputra (Patna) have a rather special character, and perhaps reflect contemporary Persian influences. There have been excavated here parts of a very massive wooden city wall; a timbered flooring extending for three hundred and fifty feet; a series of wooden platforms apparently intended to support a stupendous superstructure; evidences of a pillared hall with eighty polished stone columns; a magnificent stone capital, a stone voussoir from an arch, a stone griffin bracket, and other fragments. It is thought that the plan of the palace was identical with that of the Achaemenid palaces at Persepolis; Arrian speaks of Aśoka's palace as no less magnificent than those of Susa and Ecbatana.

Suṅga, Kuṣāṇa and Andhra.—Numerous reliefs from Bharhut, Mathurā and Amarāvati, foundations of ruined buildings, and excavated churches (*caitya*-halls) and monasteries (*viḥāras*) prove the existence of an architecture now advanced in scale and magnificence. The most remarkable examples illustrated in reliefs are the Sudhammā Sabhā and Vaijayanta palace from Bharhut (Plate I, figs. 4 and 5), the exquisite early shrine from Jagayyapeta, the tree temples from Bharhut, Sāñci, Mathurā and Amarāvati, and a little structural domed shrine from Amarāvati. Of the "caves," the *caitya*-hall and *viḥāra* at Bhājā, the great *caitya* halls at Kārli and Nāsik and the Jaina monasteries of Udayagiri and Khaṇḍagiri in Orissā, are most noted. Of stūpas, those of Bharhut, Sāñci, and Amarāvati; while in Gandhāra, both at Taxila and in Afghanistan and extending thence to Turkistan a little later, there are countless remains of stūpas richly decorated with Graeco-Buddhist sculpture, and many ruined monasteries. Connected with the stūpas are their railings and gateways, of which those at Sāñci are perfectly preserved, and those of Amarāvati are well-known from the British Museum series. Most surprising is the

evidence of a seal discovered at Patna, with a Kharoṣṭhī inscription of not later than the second century A.D.; this seal represents a very tall straight-edged *śikhara* shrine, doubtless of brick construction; a true arch above the entrance doorway is clearly shown, and the *cella* contains a seated image of Buddha. The representation closely resembles the well-known Buddhist temple at Bodhgayā, and may be it. In any case it provides a strong corroboratory argument for a dating of the Bodhgayā temple, substantially in its present form, from the reign of Huvīṣka in the second century A.D., as originally suggested by Alexander Cunningham.

A famous structure often referred to at a later date by the Chinese pilgrims was the "stūpa" of Kaniṣka near Peshawar. From the foundations of this great building has been recovered an inscribed silver reliquary made for Kaniṣka himself, and containing relics purporting to be those of the Buddha. According to the Chinese account the basement rose in five stages to a height of a hundred and fifty feet, the wooden superstructure to four hundred more, and the iron mast with twenty-five copper umbrellas eighty-eight feet more.

Gupta About A.D. 320-600.—Of this period both Buddhist and Hindu buildings in stone or brick and excavated shrines are characteristic. The most distinctive temple type is that consisting of a square *cella*, with plain walls and flat roof, and either surrounded by a pillared hall, as at Bhumara, or preceded by a small and graceful pillared porch as at Sāñci. Tigowā, Pithaora and Nāchnā-Kutharā. The little temple at Sāñci well illustrates the fine proportions and appropriate use of ornament characteristic of the early Gupta period. The most important related groups of excavated shrines are those of Udayagiri in Gwalior State (Hindu), and Elūrā (Viśvakarmā *caitya* hall) and Bāgh and Ajaṇṭa (Caves XVI., XVII., XIX., especially the last, with its well-known magnificent façade). Farther south, at Bādāmi, Aihole and Paṭṭadakal three of the earliest Cālukyan buildings are of Gupta date or a little later. The Lāḍ Khān, c. A.D. 450, is constructed of slabs and pilasters in archaic style; the Durgā temple, about a hundred years later, is apsidal like a *caitya*-hall, combined with a northern Nāgara *śikhara*. Very interesting apsidal brick temples survive at Ter in the Sholāpur District, and Chezārā in the Kistna District.

The northern *śikhara* shrines, usually brick towers with stone doorways, are beginning to appear. For the most part the earliest examples are straight-edged, or nearly so, and with angle *āmalakas* at every course, or every second or third course. The example at Deogarh is entirely of stone; not less important is the brick tower at Bhitargāon, with a recessed frieze of carved brick, and terracotta panels of Brahmanical subjects. A little later than the Gupta period, but suitably mentioned here, is the brick tower at Sirpur, probably the most exquisite example of a richly decorated brick structure to be found in all India. The monastic university of Nālandā was found by Bālāditya at the close of the fifth century. Hsüan Tsang saw there a great brick temple over three hundred feet in height; and at Bodhgayā, the temple above referred to as of Kuṣāṇa date. The great Hindu temple at Konch, very near Bodhgayā and similar in many details, though the spire is curvilinear, may well be of Gupta date.

MEDIAEVAL

From the Gupta period onwards it is convenient to describe the architecture in terms of the three great styles, Nāgara (northern or "Indo-Aryan"), Vesara (later Cālukya, Hoysāla and Solāñki, of the Dekkhan, Mysore and Gujarāt), and Drāviḍa (southern Dravidian) with separate mention of Kaśmīr, and of the civil architecture of Rajputāna.

Nāgara.—Here the most conspicuous feature is the curved outline of the *śikhara*, which is composed as in the south of many storeys representing reduplicated cornices and roofs; but owing to the great compression of each storey, the vertical lines of the whole form are far more conspicuous, at least in the later types, than are the horizontal lines of the successive cornices. The tower, usually square, rarely circular in plan, is corbelled inwards until the sides nearly meet, the whole is crowned by a huge ribbed lenti-

cular stone, the *āmalaka* which supports the usual vase finial; at successive stages along the edges of the tower will be found quarter- or angle-*āmalakas*, one at each stage in early types, more widely separated later. These angle *āmalakas* are clear evidence of the roof-like character of each stage; and indeed, nothing is more characteristic of Indian architecture, nor more valuable for the elucidation of its history, than that the ornamentation consists essentially of reduced, simplified, or archaic forms closely related to those of the whole building. The porch or *maṇḍapa* is usually open and pillared, sometimes roofed with a dome, more often with a pyramidal roof composed of repeated cornices. In the Nāgara style, a barrel-vaulted roof is very rare, but examples are to be seen at Gwalior (Teli-ka-Mandir), and in Orissā (Vaital Deul at Puri). The early capital with adorsed animals disappears after the Gupta period, to be replaced by square cushion capitals of various kinds or by a development of the pot-shaped capital into a brimming vase (*pūrṇa kālāśa*) with lotus flowers, and foliage falling from the mouth onto the four corners; in cave temples, e.g. the great Śaiva shrines at Elephanta, near Bombay, a globular *āmalaka* capital is highly characteristic; there may be a derivative connection between this form and that of Viṣṇu's mace.

The most southerly extension of the style is found at Bādāmī, where the apsidal Durgā temple, perhaps of Gupta date, has already a northern *śikhara*. Here, and in several other places, the two styles can be seen side by side. It is however in Orissā, Bundelkhaṇḍ and Rājputāna that the finest and most continuous series is to be found. In Orissā the series shows a continuous development from the 8th to the 13th century; the Paraśurāmeśvara and Lingarāja temples at Bhuvaneśvara, the Sun temple at Koṇārak, and the Jagannātha at Puri are most remarkable, and the beauty and grandeur of most of these it would be difficult to exaggerate. At Khajurāho in Bundelkhaṇḍ there is another magnificent series, dating between 950 and 1050, e.g., the Kandārya Mahādeva temple is the finest; the effect of height, actually 116 feet over all, is increased by the great depth of the basement, and by the vertical lines of the reduplications of the main form upon itself. Here, as well as in Orissā, and elsewhere, the temples are covered with figure sculpture.

From Bengal and Bundelkhaṇḍ the style extends through Rājputāna (where the Siddheśvara at Nemawār, Indore State, is of prime importance and one of the best preserved mediaeval monuments extant) to the Pañjāb (Āmb and Kāfir Kot), Kāngrā and Kulū (Baijnāth, Masrūr, and Bājaurā). Modern temples in the Nāgara style include the Viśveśvara at Benares, the funeral chapels at Gwalior, the Jugal Kisor and Madan Mohan at Brindāban, and amongst the many alms-halls, *ghāṭs*, wells and temples built by Queen Ahalyā Bāi (1765-95), the Gr̥ṣṭaneśvara temple at Elūrā.

Vesara, Hoysāla and Solanki, 10th-13th Century.—After the recovery of the old Cālukyan territory by a later branch of Cālukyas or Solankis in 973, a new style of architecture came into being in the Dekkhan and flourished during the 11th and 12th centuries. Another branch of the Solanki family held Gujarāt from the 11th to the end of the 13th century. During the 12th and 13th centuries the Hoysāla dynasty ruled Mysore. The Vesara style of architecture is found throughout the area referred to. Conspicuous features are low elevations (contrasting with those of the high Nāgara and Drāviḍa *śikharas*) and wide extension, the star-shaped plan of the cella, the grouping of three shrines about a central hall, low pyramidal towers, elaborated pierced windows, elevated basements with very richly decorated courses, and in general an excess of ornament. In the Dharwār district, the Doḍḍa Vasavanna is perhaps the most elaborate building in western India. In Mysore the most celebrated shrines are those of Doḍḍa Gadavalli, Somnāthpur, Belūr, Balagami, and Halebid, and the Jaina *bastis* at Śravaṇa Belgola.

In Gujarāt the most famous temple was that of Somnāth (Kāthiāwār), wrecked by Maḥmūd of Ghazni in 1024. At Anahilpattana the greatest royal builder was Siddha-rāj (1093-1143). Here as at Vāḍnagar and Mudhera are the ruins of important shrines. A special characteristic of the local style is the erection of *kirtistambhas*, or "Towers of Glory"; the finest of

these, in the Chitor Fort, was built in 1440-48, to commemorate the erection of the Kumbhasvāmi temple.

More famous are the Jainā temples at Mt. Abu in Rājputāna, particularly those of Vimala Shhāh and Tejāhpāla respectively, A.D. 1032 and 1232. These are domed shrines with pillared halls, built entirely of white marble, carried up the mountain with infinite labour from the plains below. The most remarkable

BY COURTESY OF ARCHAEOLOGICAL DEPT., SOUTHERN CIRCLE, MADRAS, INDIA
TWO DOLMEN SIVA TEMPLES AT KAMBADUNI, ANANTAPUR DISTRICT

features are the domed ceilings, with deeply undercut, fretted marble which has been compared to "frozen lace," with a central pendant.

Deservedly famous too are the Jainā temple cities of Girnār and Sātruñjaya, with buildings ranging from the 13th to the 19th century. These cities of temples built on hill-tops were exclusively places of pilgrimage, never otherwise inhabited. Of ordinary cities there are well preserved remains at Dabhoi and Jhīñjuvād. At the somewhat later capital of Ahmadābād the architecture is almost entirely Mohammedan; but it was executed in the same style and by the local craftsmen, adapted only to Muslim necessities by omission of figure work from the niches.

Drāviḍa.—In southern India, as the Maṇḍagapattu inscription of the great Pallava king Mahendravarman I. (600-625) informs us, temples had been built of brick or timber, reinforced by metal and mortar; only from the seventh century onwards do we meet with excavated monolithic and structural temples in stone. It is difficult to characterise the style in detail, on account of the continuous development, of which the best account has been given by Jouveau-Dubreuil (see Bibliography). Markedly contrasting with the Nāgara style of the north, are the conspicuous horizontal lines of the towers or spires, produced by a repetition of heavy roll cornices, dividing one storey from the next; each storey is decorated with little pavilions (*pañcaram*) or dormer windows (*kūḍu*). The walls are often plain, with narrow pilasters, gradually elaborated as the style develops. The pillars are at first supported by lions, and polygonal in section, with a thin flat abacus and roll brackets, later a pendent lotus. The summit of the roof is always a square, circular or polygonal dome (*stūpī*), or barrel vaulted and apsidal, in the latter case appropriately designated as *gajapṛsthā* ("elephant's back"). The temple is always enclosed by a high wall or walls (*prākāra*), pierced by four gateways (*gopura*); in some cases, as at Madura, the enclosure becomes a veritable sacred temple city wherein all the activities of life are carried on.

The early Drāviḍian style (Pallava and early Cālukya) is admirably illustrated in the Pallava temples of Māmallapuram (the "Seven Pagodas") and Conjeevaram in the east and early Cālukya shrines at Bādāmī, Aihole and Pattadakal in the west. The visitor should make every effort to visit the "Seven Pagodas" at Māmallapuram, which are easily accessible from Madras. The earliest monuments are cave temples at Uṇḍavalli; then come the Seven Pagodas and cave temples in the seventh century, and in the eighth, the structural temples of Conjeevaram, and the "Shore temple" at Māmallapuram, after which the style passes gradually into that of the Coḷa period. In the west, at Bādāmī and Aihole, there are six cave temples, two Jainā and four Brahmanical, one dated 578. The structural Mālegitti Śivālaya, c. 625, magnificently situated on the summit of a hill, is perhaps the purest and

best example of the style; it is small and massive, but finely proportioned. Much larger, and magnificent both in design and execution are the two great temples due to the queens of Vikramāditya II., datable about 740. Of these the Virūpākṣa, still very massive, was probably built by workmen brought from Conjeevaram, where the Rājasimheśvara (or Kailāsanātha) temple had been built not long before the city fell to the Cālukyan invaders; we know from an inscription that Vikramāditya was so much impressed by that great shrine (which still stands, unused, but in almost perfect preservation) that he not only refrained from destruction, but himself made offerings and overlaid the images with gold. In A.D. 753 the Rāṣṭrakūṭas invaded and occupied the Cālukya territory. No doubt as a result of this invasion workmen were carried off, and this probably explains the form of the great Kailāsanātha rock-cut shrine at Elūrā which is evidently modelled closely on that of the Virūpākṣa at Bādāmi. This wonderful temple, cut out of the side of a hill, is a complete model of a structural building, and together with the somewhat later and very similar Jaina Indrasabhā also at Elūrā, marks the farthest limit of the northward extension of the Drāviḍa style. The Bhoganandīśvara temple at Nandi, c. A.D. 800, affords another important example of a Rāṣṭrakūṭa building in Drāviḍa style.

Cola and Pāṇḍya.—In the Cola period the tower of the central shrine is typically developed to a great height, by a reduplication of the corniced storeys, as in the great *vimānas* at Tanjore, the centre of Cola power, and at Gaṅgaikōṇḍapuram, both of early eleventh century date. The former is 190 feet in height. There are also good examples of the style at Polonnāruva in Ceylon, built during the Cola domination. The Pāṇḍya period is characterised by the development of the great gateways, with a lower storey of stone and super-structure of brick, covered with brick and stucco images plastered and painted. They have the aspect of veritable sky-scrapers, and completely dwarf the main shrines.

Vijayanagar and Madura.—These later phases of the southern style are characterized by the development of the great pillared halls (*maṇḍapam*). The monolithic pillars are cut into groups of slender columns, or are provided with elaborate brackets, nearly the full size of the pillar itself, and representing leogriffs (*yālis*), or horsemen on rearing horses attacking leopards, or consisting of dancers, deities or effigies of founders. Of the earlier series, the great shrines at Vijayanagar, Āvaḍaiyar Kōyil and Tāḍpatri are the most remarkable; of the later, the great buildings of the Nāyyaks of Madura, dating from the seventeenth century are well-known to all travellers in India. It is perhaps rather unfortunate that the Drāviḍa style is best known by one of the latest examples, the Minākṣi shrine at Madura; the whole complex is indeed impressive, but it gives little idea of the earlier purity of Drāviḍa design. Temple building and restoration continue in southern India, and in Ceylon, today.

Kāśmīr.—In Kāśmīr, which had been a dependency of the Kuṣāna empire, and later an independent kingdom, the prolific building period extended from the 8th to the 13th century. The style has local peculiarities; the double pointed pyramidal roof, pediments enclosing a trefoil niche, lantern ceilings, fluted columns with Doric or Ionian capitals, and large peristyles are very characteristic. The architecture here preserves a certain quasi-classical character derived from Gandhāra, and not seen in the rest of India, though often recognizable in Central Asia. At Parihāsapura a large Buddhist stūpa with a double platform, and stairways on each side is contemporary with the Javanese Borobudur; and there are temples of extraordinarily massive construction, one flooring stone consisting of a single block 14×12×6 feet. Two great temples at Avantipur are due to Avantivarman. The court of the Mārtāṇḍa Sun temple is about 220×142 feet; that of the Pāṇḍu-kund in Jammū about 191×121 feet. Related architectural forms are found at Malot in the Punjab, and at Gop and some other places in Kāthiāwār. But the trefoil arch, derived from the section of a *caitya*-hall, while confined to Kāśmīr, is an important architectural form, occurs also at Sarnāth, Sīrpur and elsewhere.

Rājput Civil Architecture.—Twenty or thirty royal residences, a number of cities, and ghāṭs, preserve from the 15th century to the present day a civil architecture of extraordinary grandeur and beauty; the architecture of Faṭhpur Sikri, too, is almost purely Hindu in character, and essentially Rājput adapted to Mohammedan requirements (see MOHAMMEDAN ART). The Rājput style is less intricately ornamented, but of more monumental dignity than the better known Mohammedan palaces of the 17th century.

The earliest well preserved palaces are those of Chitor and Gwalior, the latter magnificently situated on the edge of a great flat-topped hill, with several great gateways guarding the approach, and a small palace, the Gujari Mahall at the foot of the hill. Begun under Mān Siṅgh in the 15th century it was completed during the Mughal occupation in the 17th. Bir Singh Deva's 17th century palaces at Datia and Orchā are almost equally splendid. The palace at Amber, 17th century, is more nearly like Mughal work, and so too the lovely marble pavilions by the lake at Ajmere. The whole city, palaces and island palaces of Udaipur (c. 1600-1740) are of romantic beauty. The Jodhpur palace, 17th century, is situated on the top of a rock dominating the city below, and guarded by bastions of tremendous size. The modern city of Jaipur, the Benares ghāṭs (with buildings mainly of the 18th century), the ghāṭs at Maheśvar and Ujjain, the modern work at Bulandshahr, Mathurā, etc. (see Growse, and Sander-son, in Bibliography) and the cenotaphs of Rājput princes in many capitals, are all evidences of an architecture by no means lost, but still practised. The little modern railway station at Alwar shows how this tradition can be adapted to present day requirements; the new city at Delhi is a monument of the neglect of indigenous resources. (See DELHI; NEW DELHI.)

CEYLON

The earliest buildings in Ceylon are dāgabas or stupas, those of Tissamahārāma dating from the 3d or 2d century B.C., the Yaṭṭhāla Dāgaba being the most important of the series. At Anuradhapura, the capital from the middle of the 3d century B.C. to the end of the 8th A.D., the Thūpārāma was the first dāgaba to be erected, and like the Maha Seya at Mihintale it was built by the great Devānampiyatissa, the contemporary of Aśoka, and recipient from him of the branch of the Bodhi-tree which was planted with great ceremony at Anuradhapura, and may now be called the oldest living historical tree in the world. To Duṭṭha Gāmaṇi, early in the 1st century B.C. are due the Ruanweli and Miriswetiya Dāgabas, and to Waṭṭa Gāmaṇi in the same century the Abhayagiri Dāgaba, later confused with the Jetavana built by Mahasena at the end of the third century A.D. All these dāgabas can be seen at the present day, but they have suffered both from ruin and from restoration. The famous Lohapāsāda, the Brazen Mansion, built by Duṭṭha Gāmaṇi as a monastery is now represented only by the monolithic pillars of the basement, twelve feet high and covering an area 250 feet square; the pyramidal superstructure was of wood with a brazen roof; originally of nine storeys, it was later burnt and rebuilt with only five.

The natural fortress of Sigiriya was occupied in the 5th century by a parricide king who built a palace on the summit, and a remarkable walled gallery, still usable, as a means of access.

As a result of the Tamil invasions the capital was removed to Polonnāruva which became the capital from 781 to 1290, which period includes a short interlude of Cola occupation. The most remarkable and important buildings are due to Parākrama Bāhu in the 12th century (1153-86). The Thūpārāma is a rectangular brick temple in Dravidian style, but with vaulted arches and narrow triangular windows like the early towers in northern India. The Northern Temple (so-called Demala Maha Seya) contained frescoes (*Jātaka* subjects). In the Jetavana group at the other end of the city, the Laṅkātilaka is the largest Buddhist temple in Ceylon. The Potgul Vihāra is a circular building in which Parākrama Bāhu used to sit and listen to the reading of the *Jātakas* by his chaplain. The Sat Mahal Pāsāda is a solid pyramidal seven-storeyed brick structure like the traditional representations of Mt. Meru; on each storey are niches with brick and stucco

Architect (sthapati) drawing design for new construction on an existing wall, at Āuvadaiyar Kovil, A.D. 1907

The architecture of Siam is not well known. No edifice of importance survives from the Dvāravatī (Mon) period, but the Brah̃ Paṭhamacetiya reliefs have decorative representations of buildings with caitya arches (*kūdu*), suggesting, as in the case of the contemporary pre-Khmer architecture of Cambodia, direct connections with Indian originals. At Labapurī and Ayuthiā, up to the 14th century, the architecture is of directly Khmer inspiration; Wāt Mahāthāt at Labapurī is a good example. Simi-

larly at Svargalok and Sukhodaya, buildings dating before the establishment of an independent Thai kingdom, e.g., the Wāt Mahādhatu at Svargalok, and Wāt Brah Bāy Hluang at Sukhodaya, are equally Khmer, and the sculptures found in them are analogous to those of the Khmer school at Labapuri. The 13th century Wat Kukut at Lāmbūn (a pyramidal tower apparently related to the Sinhalese Sat Mahal Pāsāda at Polonnāruva) and the Wat Chet Yot at Xieng Mai (modelled either directly after the Indian temple at Bodhgayā, or more likely on the 13th century Burmese copy at Pagan) belong to the last days of Mon government in the north. The remains of the Wat Keo at Jaiyā in the far south belong to the school of Śrīvijaya. It is only after the foundation of Ayuthiā that a distinctively Siamese architecture develops, and as seen at Ayuthiā and Bangkok, this is characterised by slender, aspiring, and pointed forms. (See SIAM.)

CAMBODIA

Pre-Khmer or Khmer Primitive.—The history of Indian architecture in south-eastern Asia can be followed in Cambodia better than anywhere else; here, despite the fact that with the disappearance of wooden architecture more abundant than that in stone, the sequence is relatively complete. In the Khmer primitive, or pre-Khmer (as different authors interpret it) architecture of southern Cambodia, dating from the 6th and 7th centuries (when permanent material such as brick, laterite, and stone were just coming into use), we find a series of buildings which exhibit striking analogies with those of the early Cālukyas of the western Dekhan, as well as with those of the Pallavas, and even with the earlier style of the Andhras. M. Parmentier, in his two fine volumes entitled *L'Art khmer primitif*, has argued, probably rightly, that both these early Cambodian and the contemporary Indian forms are developed locally from common earlier Indian sources. A slab-built cella at Hanchei recalls the small shrine on the roof of the Lāḍ Khān at Aihole; it was once perhaps surrounded by a pillared hall as at Bhumara. Another very elegant square cella at Prēi Kuk has shallow pilasters, and characteristic Indian cornices with dormer-arches framing Gandharva heads, and is quite Pallava in appearance. Here also, and at Bayang there are high brick towers suggesting such Gupta types as Deogarh or Bhitargaon; at Mahā Rosēi there is a granite shrine of Pallava type.

Classic Period, Khmer.—From the 9th to the 12th century and even later, Cambodian architecture develops still in brick and laterite, but more characteristically in stone. Indian forms are departed from, or freely modified, and local features appear, so that a truly national architecture comes into being. Unlike anything in India are the half-vaulted arches with curved stone sloping roofs imitating tiles, and so too the huge faces or masks on the sides of the early towers of the Bayon and Angkor Thom gateways. On the other hand the later towers develop as in India by a reduplication of storeys, vertically compressed, and many motifs, seemingly novel, for example the Garuḍa caryatides of the Prāh Khān walls and the Angkor Thom terrace have really older Indian prototypes. The classic Khmer architecture is widely distributed in northern Cambodia, perhaps the original seat of the Khmers. The best known monuments, out of hundreds still in existence, are the city of Angkor Thom and the neighbouring temple of Angkor Wāt ("Angkor" is a corruption of Sanskrit *nagara*, city or capital; Wāt or Vāt, a later Siamese term for any Buddhist monument). The city, occupied about A.D. 900, is of great extent, and contained within a moat, crossed by five causeways with parapets consisting of gods and giants holding the body of a giant Nāga; these causeways lead to triple gateways large enough for the passage of elephants, and from these proceed five roads to the heart of the city. Near the city are the previous capital of Prāh Khān, and other shrines such as the Néak Péan, and Phnom Bakeng, and Angkor Wāt, and many artificial lakes. The city is situated in the plains, among the rice-fields and near the great lake, both necessary sources of food supply for a great population. There the most important structures are found to be the great terrace running along the public square in front of the palace site; and numerous temples, of which the Bayon is the most remarkable, others being known as the Baphuon, and Phimānakas.
